Within the past few years there has been much written concerning the prevention of cancer, its early diagnosis and its proper treatment. It is interesting to see just what fruits this propaganda is bearing. Unquestionably many more persons with premalignant conditions are consulting the surgeon and dermatologist than in former years, but that the situation is yet far from perfect will be revealed by a consideration of the following cases.

During the past three years I have been consulted by thirty-two private patients for malignant conditions of either the skin or mucous membranes of the mouth. Of this number only six consulted me for early, untreated stages of cancer. One of these had a cancer of the under surface of the tongue, while the remainder were suffering from cancer of the face.

The faults in handling the other cases naturally group themselves under three headings: first, neglect on the part of the patient; second, faulty diagnosis on the part of the physician, and, third, improper or insufficient treatment by either physicians or quacks.

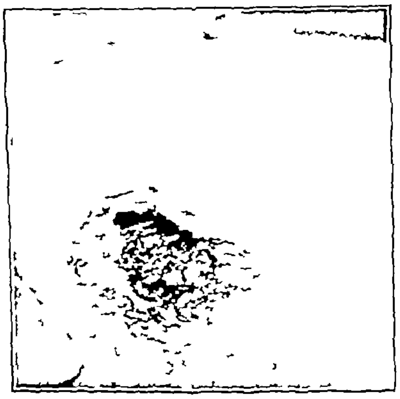

Fig. 1.—A prickle cell cancer of the cheek which was mistaken for a gumma.

In nine instances, patients had neglected themselves without seeking medical advice. One intelligent man had suffered from a cancer of the scalp for nineteen months, four patients had superficial growths of either the face or neck for over two years, one man had carcinoma of the lip for eight months, two had cancers of the face for six years, and one woman had five neoplasms of the face for seven years before seeking aid.

In this series there were six cases that had been wrongly diagnosed by the attending physicians.

One case of a basal cell growth developing in the nasolabial fold of a man aged 40 was called lupus vulgaris and treated on the expectant plan for some years.

In another instance the development of a fungous cuboidal cell neoplasm in a chronic varicose ulcer was unrecognized for three months.

The third case occurred in my own practice. A man aged 56 was referred to me by an excellent surgeon with a diagnosis of gumma of the cheek. The patient denied any venereal infection, and the Wassermann test was negative. However, he had pigmented scars over the upper third of both shins, and the tibiae were thickened and roughened. On the other cheek was a depressed scar which he stated resulted from an ulcer that remained unhealed for six months. The lesion for which he was referred was horseshoe shaped, at one end it was cleanly punched out for a considerable depth, and at the other end the skin overhung the base, which was composed of a fairly clean granulation tissue which was not friable. There was no history of bleeding. The edges were considerably indurated, but there were no cancer nodules or plugs, and there was a zone of inflammatory redness for over half an inch beyond them. In view of the other findings I considered that the condition was syphilitic, so at once administered a full dose of salvarsan, with the result that the ulcer at once stopped discharging, and apparently began to fill in from the base. At the end of two weeks another injection of salvarsan was administered, but this time no improvement took place, and it was very shortly evident that the lesion was spreading. Ten days after the last injection a hard pearly nodule appeared at the border of the ulcer and this was excised with the electric cautery, and stained. It disclosed typical prickle cell epithelioma.

In the fourth case a man presented himself with an indurated raised lesion about the size of a quarter on the edge of his tongue next a sharp tooth. The diagnosis of cancer was made and a radical operation advised but the patient was not satisfied and went to another city where he was put on injections of mercury. When he returned to Washington three months later the whole floor of the mouth and most of the submaxillary glands were involved.

The fifth case was one of retrotonsillar lymphosarcoma which was seen by a throat man and diagnosed as cold abscess despite a mass of adherent glands in the submaxillary region. This was lanced many times before the correct diagnosis was made.

The last instance was one of typical carcinoma of the tonsil which was first treated for quinsy. Later the patient received several injections of salvarsan and at the same time received one "massive dose" of Roentgen rays on the supposition that it might be malignant. Just what was the excuse for combining both methods of treatment would be rather interesting to know.

Twelve cases were either improperly or insufficiently treated after a correct diagnosis was made. In several instances more than one faulty method of treatment was employed.

Four cases had been treated by caustics.

One man with an early basal cell neoplasm of the nasolabial fold was treated by caustic potash, with the result that the lesion was spread

was probably just as well considering the results obtained In this case one would guess that the amount of radium used was too small, and simply acted as a stimulant

Still another patient with an extensive carcinoma of the floor of the mouth had been referred to the same physician, and radium had been applied to the trouble within the mouth with marked benefit, all of the lesion being at least healed over The glands of the neck, however, were treated by the external application of radium with the most disastrous results, for they were simply stimulated, and speedily ruptured through the skin, as well as invading the deep planes of the neck Here again a possible operable case was made inoperable

The last case was that of an out of town physician who had a superficial basal cell cancer of the left cheek which had been treated with carbon dioxid snow, partially excised, and then radiated, all without benefit Several treatments with radium at the hands of another exponent resulted in the temporary disappearance of the lesion, but each time it speedily reappeared After the last course a nodule, not more than 7 millimeters in diameter became at least 5 centimeters in diameter within two or three weeks

In view of the very bad way in which at least three of these cases were handled, one must naturally wonder whether some of the so-called radium experts are not on the same plane with those advertising various nostrums, both local and internal, for the cure of the dread malady, cancer If there is any difference it rests in the fact that they are more dangerous One must also receive with some skepticism the report of cures of deep malignancies and of uterine fibroids

CONCLUSIONS

1 The public is not yet sufficiently educated as to the importance of attending to superficial sores that will not heal

2 While it must be admitted that some cases of superficial malignancy are difficult to diagnose, still entirely too many of them are mistaken for other affections, even by experienced physicians All suspicious growths should be positively diagnosed at once

3 Many cases are not treated radically enough, it should always be remembered that insufficient treatment of whatever kind is the worst possible thing for a patient suffering from a malignant condition

4 Radium, even in large doses, and when administered by some of its greatest advocates, is by no means infallible in the superficial cases that it is stated to cure

---

The Extinguishing of Small Gasoline Fires—As a result of a series of tests, the British Fire Preventive Committee has found that a mixture of sawdust and sodium bicarbonate, in the proportion of twelve of the former to ten of the latter, has advantages over sand and similar materials as an extinguishing medium for small gasoline fires The sawdust should be free from shavings or chips of wood, but does not require to be either dried or damped. The mixture is best kept in bins holding eight bushels In regard to the application of the mixture, the committee recommend that, in order to be thoroughly effective, it must be applied rapidly and in large quantities but systematically, so as to produce a curtain effect —*Lancet* London

CONTRIBUTIONS TO THE MOVEMENTS OF THE EMPTY STOMACH

XXXIV A NOTE ON THE MOVEMENTS OF THE EMPTY STOMACH IN CERTAIN PATHOLOGIC STATES *

A B LUCKHARDT, M D
AND
W W HAMBURGER, M D
CHICAGO

Up to the present, with the exception of five papers,[1] none of the contributions of this series has dealt with the activity of the empty stomach under any but normal physiologic conditions It is perfectly plain, however, that the simple methods used in working out the essential features of the mechanism of hunger can be used equally as well in studying gastric motility under diverse pathologic conditions, especially when the general symptoms of the malady, disorder or disease refer directly or indirectly to pathologic states present in or involving the stomach We refer chiefly to such disorders and diseases as gastric or duodenal ulcer, carcinoma of the stomach with or without pyloric obstruction, and acute gastritis In short, the activity of the empty stomach might be profitably studied in conditions involving polyphagia on the one hand and anorexia on the other, as well as in those conditions which deal with pain referable for the most part to the epigastric region Such a study made by a person having ready access to the wealth of material found in the larger hospitals would not only be of value in corroborating or modifying the interpretation of experimental work obtained from dogs, but also might lead to results that would direct therapeutic measures in the proper direction in the disease under observation There is no question that the method employed would aid in the diagnosis and differential diagnosis of various gastric disorders

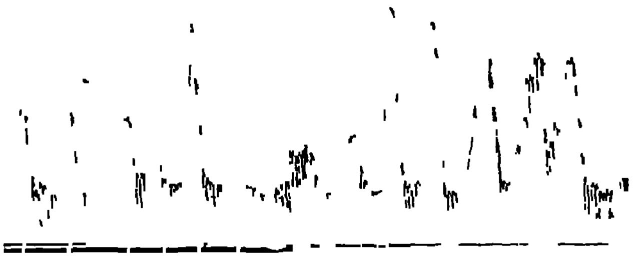

Fig 1—Record of the stomach contractions in Case 1 Patient pressed down key every time he noted an abdominal discomfort. As can be seen from the record, the abdominal discomfort coincided with the contractions of the empty stomach.

The present communication has a triple object

1 To point out to those interested in the clinical side of medicine the simplicity of the method, the small cost of the apparatus requisite for obtaining reliable and accurate results, and the value of the results obtained to the physiologist and to the clinician A

limited experience has shown that the method is feasible for bedside work Aside from the kymograph, most of the apparatus is found in every hospital, and what is not there can be easily made, or bought for a few dollars Patience is a requisite of importance if anything of value is to result Sacrifice of some time is a prime essential

2 To put on record the result of an experiment on man beautifully corroborating the results obtained from dogs by one of us[2] during an investigation as to the cause of polyphagia of diabetes mellitus and pancreatic diabetes

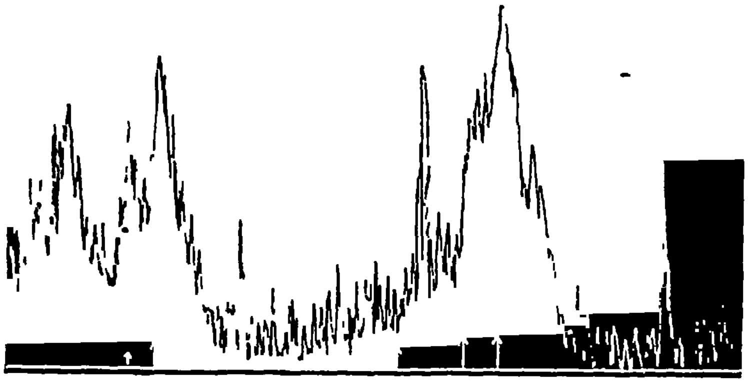

Fig 2—Record of the stomach contractions in Case 2 The various dots on the tracing indicated by an arrow represent occasions when the patient experienced abdominal discomfort the same in type as when he was hungry As can be seen from the tracing, the contractions are moderately powerful, resembling in type those obtained by Elsesser in dogs following experimental pyloric stenosis

3 To record the results obtained from the human stomach under several other pathologic conditions—results which check with our conceptions as to the nature and cause of hunger

We earnestly invite the reader to examine the simplicity of the method described in detail elsewhere,[3] and we pass, therefore, directly to the results obtained by us in three patients under the care of one of us (W W H)

REPORTS OF CASES

Case 1—M O, man, admitted to Michael Reese Hospital, Jan 29, 1914, complained of a slight loss of weight since the onset of his illness three or four years ago, which consisted of "pain in upper abdominal region" during the day (from 8 to 9 a m) and night He characterized the pain as a dull ache which did not come on till late after meals Aspiration seven hours after a motor meal was negative The average results of two Ewald test breakfasts were quantity, 190 c c, free acid, 37, total acid, 59 Weber test on gastric contents and feces was negative A diagnosis of simple hyperchlorhydria, possibly neurotic in origin, was made, although chronic gastric ulcer was also considered

Contractions of the empty stomach taken on several successive days were not more vigorous, nor were the periods more frequent than those taken from any normal person after the same period of abstention from food As Figure 1 indicates, he felt distinctly each contraction as the pain which caused him to apply to the hospital for treatment The fact remains that after the first day of observation (which, of course, as usual the patient considered a part of the gastric treatment) his vague sensations of discomfort gradually disappeared, and he left the hospital on the fourth day expressing himself grateful for what had been done for him The patient was, therefore, judged a neurasthenic who had so focused his attention on his gastro-intestinal tract that he picked out and interpreted the sensations arising from the normal hunger contractions as the symptoms of a pathologic condition His hunger contractions were normal, and his prompt "cure" was as significant to us as it was pleasing to him Possibly an increased excitability of the central nervous system was responsible for sensations of abdominal *pain* (hunger pangs) which the normal person would *at the most* note as a vague sensation in the epigastric region and which by habit he alleviated by taking food Especially so is this likely, since introspection and unconscious exaggeration of symptoms is a favorite occupation of the neurasthenic If, then, the condition is chiefly psychic, our "treatment" might exert a favorable influence on such a patient and lead to the "cure" as described in this paper

Case 2—T K, an aged negro in Cook County Hospital afflicted with a carcinoma of the stomach without as yet grave signs of a pyloric obstruction,[4] had a tumor mass in the abdomen to the right of the median line the size of an orange, together with a gland in the supraclavicular region the size of an English walnut Two Ewald breakfasts consisting of toast and 6 ounces of tea were analyzed with the following results

First meal aspirated at end of one and a half hours, quantity, 310 c c, free acid, 18, total acid, 41

Second meal aspirated at end of hour, quantity, 120, free acid, 10, total acid, 36

The patient was emaciated, but took a lively interest in food, complaining on several occasions that the restricted hospital diet (soft diet) did not meet his hunger or appetite requirements The contractions of his empty stomach taken about eighteen hours after his last meal were fairly powerful, as can be seen from Figure 2 Since such or similar contractions in the normal result in the sensation of hunger, it is important to add that he felt during the contractions an abdominal discomfort the same as when he experienced hunger Feb 23, 1914, his empty stomach showed no signs of activity during about three hours' continuous observation (Fig 3) This deviation from the normal, however, was soon explained by an attendant who informed us that on the previous evening friends had smuggled into the hospital a bottle of wine which he drank and some cake which he munched under cover of his blankets An acute gastritis developed soon after this indiscretion, and he spent the early part of the evening retching and vomiting No doubt the acute gastritis was responsible for the absence of the usual hunger contractions and the presence of a perfectly atonic stomach Parenthetically we might note that an acute gastritis induced in a dog by giving him whisky and alcohol through a gastrostomy opening led to an atonic stomach and a cessation of the normal hunger contractions for a period of forty-eight hours But the complete results of this and similar experiments will be reported more fully at some future date Experimental work on the action of certain drugs in allaying or increasing hunger contractions has been begun, but not advanced enough for even a preliminary report

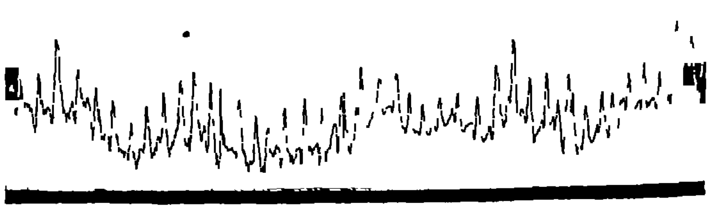

Fig 3—Record of the stomach contractions in Case 2 during an attack of acute gastritis Slight tonus variations are in evidence During the greater part of the period of observation the records show a simple respiratory rhythm

[4] Subsequent necropsy (March 7, 1914) confirmed the clinical diagnosis

Case 3—The most interesting results were obtained from C X man, aged 29, admitted to Cook County Hospital, Dec 18, 1913, and assigned to the care of one of us (W W H) Two weeks previously he had been at Mercy Hospital (Chicago) for excessive thirst, general weakness, and frequent urination He had been sick seven weeks, and during that time had lost 20 pounds He was hungry all the time and had been eating large amounts of food since leaving Mercy Hospital He was in the last stages of a severe diabetes mellitus In spite of a restricted carbohydrate and large doses of sodium bicarbonate, he was growing progressively weaker His ketonuria was marked, and his dextrose to nitrogen ratio was 1 35

Feb 11, 1914 (first trial), the empty stomach possessed good tone and showed moderate hunger contractions Five days later (Feb 16, 1914) the empty stomach showed two moderate and one powerful period of hunger contractions in less than three hours This is rather unusual, for after a twelve hours' fast, hunger periods recur about every two hours During one of the three periods mentioned above, all but a few cubic centimeters of the chloroform was expelled from the manometer, so that the graphic record is not complete The fact is significant that the patient became restless and irritable toward the end of the experiment and continually asked for food Because of this increasing restlessness and irritability the experiment was discontinued for obvious reasons

The patient went into diabetic coma five days later and died the following evening (Feb 22, 1914)

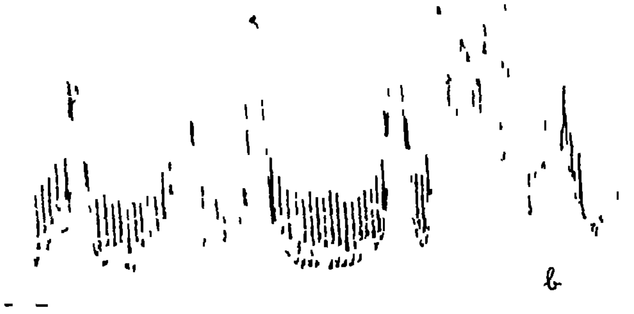

Fig 4—Record of the stomach contractions in Case 3 As can be seen the period ends in tetany at the close of which (*b*) a powerful contraction forced a considerable amount of chloroform out of the manometer

It is regretted that other duties prevented us from recording observations between February 16 and February 21 Our experiments surely indicate that the contractions of the empty stomach are responsible for the sensations of hunger experienced by diabetics We do not expect to find that other patients so near death from other causes (save in special easily explainable instances) would speak of eating as often and as freely and exhibit hunger contractions of the same severe type as shown by this patient

Incomplete as the results are, they nevertheless confirm the work on animals suffering from a fatal pancreatic diabetes when the polyphagia was attributed to the marked hunger contractions resulting from the inanition which is so prominent a feature of the disease[1] For it was shown[5] that the blood of an animal showing the polyphagia of pancreatic diabetes similar to the blood of a starved animal possessed the property of increasing the vigor of stomach contractions when such blood was injected intravenously into a normal animal

SUMMARY

The method employed in studying the movements of the normal empty stomach (hunger contractions) is feasible for use in the study of movements of the stomach in pathologic states which point either directly or indirectly to an involvement of the stomach Patients experienced no difficulty in swallowing the balloon, the apparatus necessary is simple and inexpensive, the results obtained are of great interest and value both to the clinician and physiologist

The results obtained so far warrant the following statements

1 The hunger contractions obtained from a neurasthenic conformed to the normal, though interpreted by him as painful They were neither more vigorous nor more frequently repeated than those of any normal person His prompt 'cure" justified our conclusion that we were dealing with a patient not suffering from any serious organic gastric disorder

2 Hunger contractions were obtained in a case of cancer of the stomach without marked pyloric obstruction The contractions were moderately powerful The patient was quite emaciated (in a state of inanition), but took interest in food and experienced hunger during the contractions

3 When, however, an acute gastritis is brought on by dietary indiscretions, there results a cessation of contractions of the empty stomach, and this is accompanied subjectively by a lack of interest in food and an absence of hunger (anorexia)

4 Most cachectic states are accompanied by an anorexia Further work will no doubt show that this is due to the absence of well defined hunger contractions The cachexia of diabetes mellitus, however, is accompanied by a more or less well marked polyphagia We find that the latter results from frequent and vigorous contractions of the empty stomach (hunger contractions) which are responsible for the polyphagia exhibited by patients suffering with this disease

CHYLOUS ASCITES AND CHYLOTHORAX

DUE TO CARCINOMA OF THE STOMACH

JOHN H OUTLAND MD
Surgeon to the Swedish and Bethany Hospitals
AND
LOGAN CLENDENING, MD
KANSAS CITY, MO

Chylous ascites—the occurrence of ascitic fluid which is of a milky character, and the color of which is due to the presence of chyle or of fat globules (pseudochylous)—is a sufficiently rare condition to make a case of extreme interest, both clinically and physiologically Several cases in which the condition resulted from a traumatic rupture of the receptaculum chyli have been studied by physiologists, who, assuming that they were dealing with pure chyle, have been interested in watching the effect of various diets on the composition of the chyle

In 1910 Wallis and Scholberg[1] reported three cases and reviewed the literature, collecting reports of 173 cases, but they missed the cases reported by Hall and Morton,[2] Nichols,[3] Batty Shaw[4] and Edwards[5]

---

[1] Wallis and Scholberg Quart Jour Med iii 301 iv 153
[2] Hall and Morton Northwestern Univ Bull June 1910
[3] Nichols Med News New York Nov 11 1905
[4] Shaw H B Jour Path and Bacteriol 1900 vi 339
[5] Edwards Practice of Medicine 1909

Since their article, cases have been reported by Gandin,[6] Calwell,[7] Marrack,[8] Lediard,[9] Collins,[10] and Huber and Silver [11]

The article by Wallis and Scholberg is quite exhaustive, giving an abstract of all the 173 cases of chylous and chyliform ascites and the sixty cases of chylothorax, with complete analyses of the fluid obtained in their own cases and an extended discussion of the conditions

In the cases abstracted by Wallis and Scholberg, there are seventeen in which the etiology is given as carcinoma of the stomach Of these, in three — the cases of Zawadski (1891), of Lydhecker (1893) and of Menetier and Gauchler (1902) — there also was chylous fluid in the thorax To these three we add here a fourth

REPORT OF CASE

History—W T B, man, aged 46 horse buyer, Anglo-Saxon, referred by Dr Riley of Benedict, Kan, had a father, mother and one brother living and well No brothers or sisters were dead He possibly had a syphilitic infection fifteen or twenty years before Some antisyphilitic treatment was carried on for a year, but not vigorously He used to use whisky too much but took a cure about five years before and had not used it since He had never been in tropical countries, other than Texas, where he has been within two years

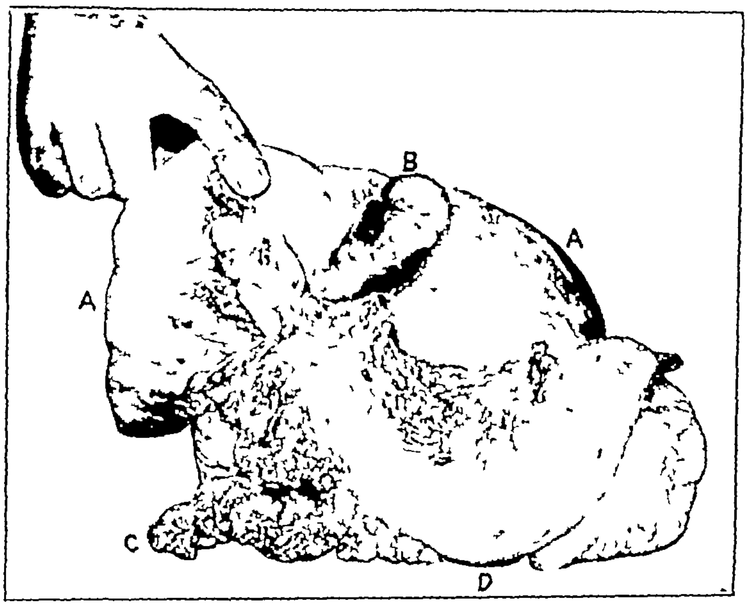

Fig 1—Gross specimen *A A* liver *B* gallbladder *C*, mesentery of the intestine filled with glands, *D* stomach, with tumor in the pyloric region

He felt well up to six months before examination (April 16, 1915) The onset of his illness was sudden One day in the afternoon he felt dizzy and vomited He did not go to bed, but was weak and dizzy and continued to feel much the same way for two months He vomited three or four times in that period He has never vomited blood In the last three months he has been troubled with indigestion, pain after meals, belching and bloating The bowels are constipated

March 27, 1915, the abdomen began to swell very suddenly, and in a few days was enormously distended It was tapped, April 1, and about a gallon of milky fluid was removed

April 8, it was again tapped, and 1½ gallons of ascitic fluid of the same character were removed

An edema of the scrotum and penis was observed at about the time of the appearance of the ascites

April 16, he was removed to the Swedish Hospital from his home in Benedict, Kan

Physical Examination—At this time the temperature was 99, pulse, 110, blood pressure, 135 Urine specific gravity, 1 020, acid, a trace of albumin, no sugar, no casts Blood hemoglobin, 105, reds, 4,000,000, whites, 17,000 Differential count of whites showed normal relationship The Wassermann reaction was negative

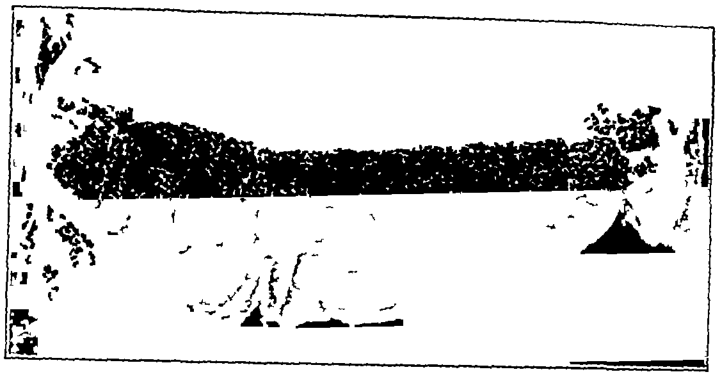

Fig 2—Duodenum, showing lacteal vessels engorged and lumpy in appearance over its surface

The patient looked old for his age His hair was white The veins on the cheeks were dilated Heart The apex was just outside the nipple line There were no murmurs A diffuse and soft swelling was on the left side of the neck just below the clavicle The lungs were clear with normal vesicular murmur everywhere except in back of left chest, where there was dulness with no breath sounds and evidence of fluid There was edema of the scrotum and penis, and enlargement of the glands in both inguinal regions The skin was slightly edematous everywhere, not more so in the legs than over the chest and in the skin of the abdomen The abdomen was enlarged, with evidences of fluid No filariae were found in the blood

Course—April 17, the abdomen was tapped, and over a gallon of milky fluid withdrawn The chest was aspirated at the same time, three and a half quarts being removed This chest fluid was clear straw colored The fluid removed from the abdomen was milky in appearance, with a tinge of pink It contained 1 9 per cent of albumin and fat, and did not react to Fehling's solution Microscopically it showed small fat globules, and small specks in constant atomic motion Leukocytes and erythrocytes were numerous

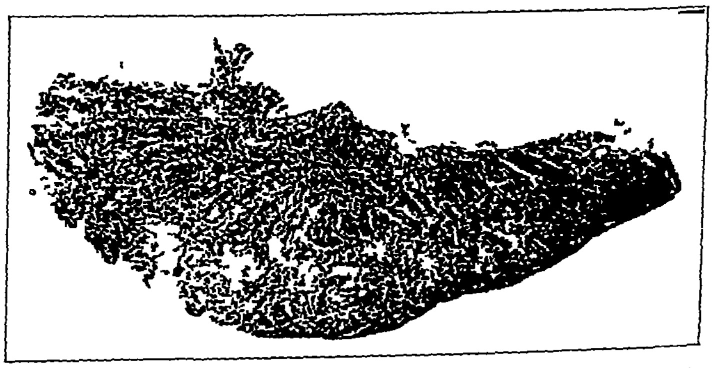

Fig 3—Small intestine, near end of jejunum, lymphatic vessels are stained with silver nitrate, note thickness of mesentery

April 23, the abdomen and the chest were again tapped Chylous fluid was found this time in the chest as well as the abdomen A swelling in the left side of the neck the size of a small orange was observed It receded in size when fluid from the abdomen was removed After the fluid had been removed, a tumor extending across the upper abdomen, above the umbilicus and more marked on the left side, could be outlined on palpation It was recorded that it felt like a tumor of the transverse colon The liver was two fingers below the costal arch

[10] Collins Ann Surg, 1913, lviii No 4

[11] Huber, Francis, and Silver, H M A Case of Acute Chylous Ascites (Non Fatty, Pseudochylous, Latescent or Milky Type) in a Boy Eight Years Old, Am Jour Dis Child, July, 1914, p 50

May 1, the abdomen and the chest were tapped A large quantity of milky fluid was obtained from each

May 12, the abdomen was tapped, 1½ gallons of chylous fluid were removed

May 13, the patient died

Necropsy.—A partial postmortem examination was made May 13, at 8 30 p m. The body was that of a middle-aged man There was no rigor mortis There was edema of the penis and scrotum There was a swelling on the left side of the neck When the abdomen was opened, about 3 quarts of milky fluid escaped The intestines were distended and covered with a lymphatic exudate The cecum and appendix were enormously distended Small lymphatic channels over the surface of the intestine were greatly distended All the glands of the mesentery were enlarged The entire mesentery was a thick mass of glands which were soft in consistency

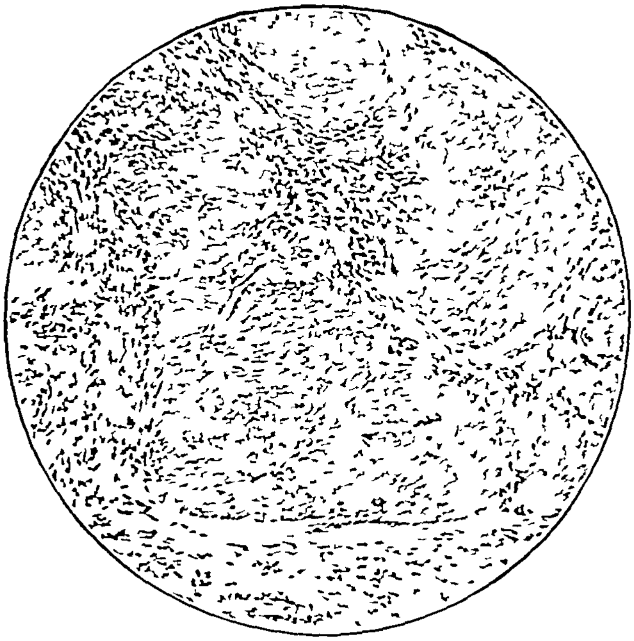

Fig 4.—Section of tumor in the stomach

The liver was enlarged and edematous The gallbladder was large There were no gallstones

A tumor was present along the lesser curvature of the stomach extending from the duodenum to well within the pylorus The glands of the gastrohepatic mesentery were enlarged. No growth was found in the rectum

Milky fluid was found in the left side of the chest. The lungs everywhere were clear and crepitant There was no enlargement in the mediastinum. There was no aneurysm The thoracic duct could not be located. The entrance of the thoracic duct into the large veins could not be made out

The entire small intestine stomach liver and mesentery with the covering of the abdominal aorta were removed in one piece

COMMENT

The case was interesting The shifting of symptoms from day to day was alone sufficient to make it such, and besides, the diagnosis was always in doubt, ranging from filariasis to thoracic aneurysm The case of Nichols,[3] of which we had a report, and in which the ascites was due to cirrhosis of the liver, influenced us to cling to that diagnosis most constantly in view of our patient's alcoholic history After he had been a week in the hospital the tumor, felt in the upper abdomen, made the diagnosis of carcinosis of the abdomen seem very reasonable

Of especial interest was the swelling on the left side of the neck just above the clavicle Was this due to an enlarged or tense thoracic duct? It was noticed that it receded in size after tappings of the abdomen or chest It extended gradually up the neck, day by day, between tappings, until it reached half way up to the sternomastoid muscle

Was there an obstruction of the receptaculum chyli, either a thrombus or a metastatic plug? We are unable to state The specimen removed from the body was taken with an especial view to a dissection of the great lymphatic duct, but while it was attempted no part of it was found The demonstration of the receptaculum chyli or of the thoracic duct is one of extreme difficulty, and rarely satisfies any one but the dissector himself After attempting it in this case we are regretfully inclined to take with a grain of salt the very glib reports of its condition made by other reporters of cases of chylous ascites

As we did not find the receptaculum in the abdomen or the thoracic duct in the thorax, we feel inclined to believe that they were not affected in this case, as a metastasis of the tumor would have been seen in either of them We believe that the chyle escaped into the abdomen through the small lymph vessels of the intestine and mesentery We know, in support of this belief, that they were all very much dilated, that the lymph nodes all through the mesentery were enlarged, and that metastases were found in the small lymph vessels of the intestine and in the nodes from every portion of the mesentery (Figs 2, 3, 4 and 5)

The fluid removed from the abdomen and the chest gave the evidence of being true chyle, it did not putrefy on standing, it did not clot, and it contained no macroscopic particles of fat A great deal is made of the differences between chylous and pseudochylous and chyliform fluids by other authors Huber and Silver make the following distinctions

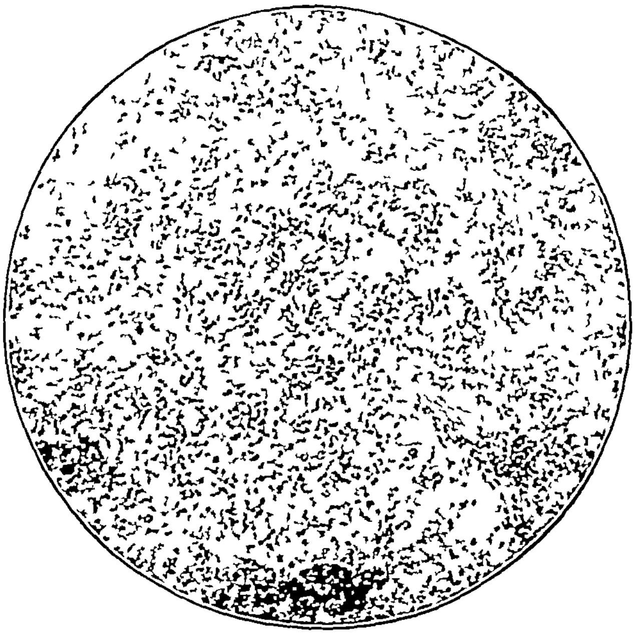

Fig 5.—Section of mesenteric gland showing metastasis

1 True chylous effusion is due to the presence of chyle

2 Chyliform or fatty, though resembling the first, owes its milky appearance to emulsified fat, the result of a fatty degeneration of cellular elements

3 In the third variety "the opalescence is not due to the presence of fatty emulsion but is caused by the

presence of opalescent substances, the exact nature of which is still undetermined "

Wallis and Scholberg have a much simpler conception of the different nature of the fluids "Chylous effusions would include, as before, those due to trauma or to the escape of chyle in diseases affecting the lacteal and lymphatic systems " Chyliform are all other kinds

CASES IN THE LITERATURE

The article by Wallis and Scholberg, as we have stated above, is the most complete monograph in English on the subject We have not attempted to confirm their references The cases which we have found in the literature not included in their article, or reported since, are as follows

Hall and Morton[2] report a case due to trauma, a wagon passed over the abdomen of a young boy Many tappings were made, and true chyle obtained The case was studied chemically by Hall in relation to diets

Nichols[3] reports a case in a man, aged 74, due to cirrhosis of the liver Two tappings were made, and 5,700 and 6,200 c c of fluid, respectively, obtained The man died, and there was a necropsy

Calwell[7] reports a case due to nephritis (?) The patient was tapped once, and 3 pints were drawn off

Marrack[8] reports two cases, one due to appendicitis and one to nephritis

Lediard[9] reports four cases, one due to tubercular peritonitis, one to Hodgkin's disease, one to heart and liver disease, and one to a malignant cyst from the pelvis

Collins[10] reports a case due to trauma

Huber and Silver[11] report a case in a child, aged 8, due to no determinable cause An operation was performed and an opportunity given to examine the intestines, when the lacteal vessels were seen engorged, as in our case A subcutaneous drainage of the peritoneum resulted in a cure They quote Gandin, a reference to which we do not have access

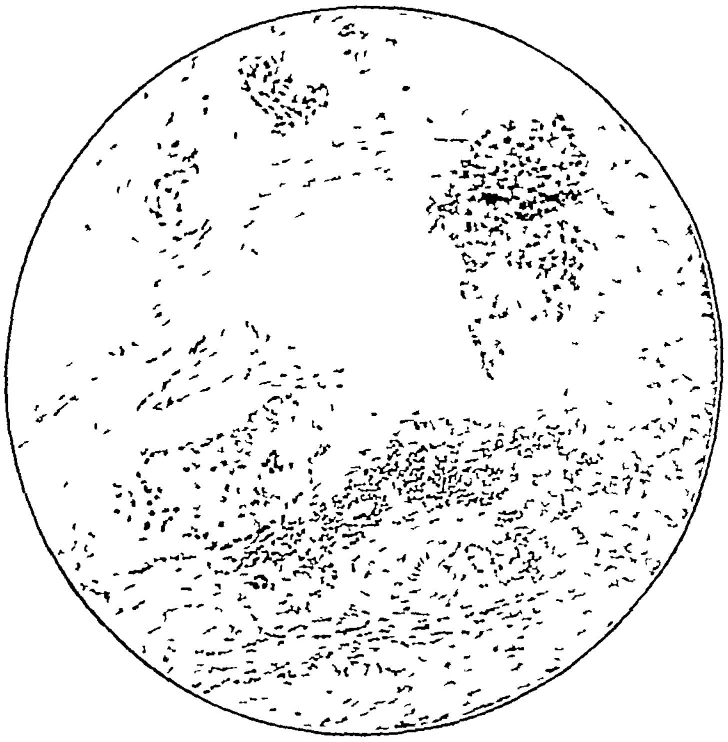

Fig 6 —Section of intestinal wall, showing metastatic plugs in the lymph channels

---

Lead Poisoning in Pottery Trades—The causes of lead poisoning in the pottery trades are the lead ingredients, of which the glazes are partly composed The most dangerous process is that of mixing the glaze, applying it to the ware and then removing the excess of the glaze from the ware, handling the ware while the glaze is still wet, decorating and painting the ware and also sweeping the rooms in which the glaze has been handled Much of the glaze is without lead and is harmless, but in a large percentage of the various pottery wares, lead glazes are used In only a few of the factories investigated by Dr Hamilton did the percentage of lead exceed 20 In certain tile works, the percentage in the glaze ranges from 40 to 60 The workmen, besides being exposed to lead poisoning, also inhale much mineral dust and suffer from the effect of great heat in the firing of the enamels—C M Price, *Modern Factory*

RICHARD DEWEY, A M, M D,
WAUWATOSA, WIS

In the latter half of the nineteenth century, many problems connected with the public care of the insane presented themselves for solution which developed conflicting views Some of these questions were the advisability of separate provision for the acute and chronic classes, the extent to which mechanical restraint was necessary or admissible, the need of establishing laboratories for psychopathologic research, of instituting training schools for attendants, of broadening and diversifying industries among the inmates and of increasing their privileges, and even of maintaining in some instances "open" instead of locked doors Among all the questions, however, that which for a time took precedence of others concerned the introduction of a new type and style of building—the substitution of modern "segregated" or "detached" buildings, domestic in style, for the antiquated "congregate" structures previously in universal use This paper is intended, among other things, to describe the new departure in architecture which was ushered in at Kankakee between 1880 and 1890

Today, when this transformation has long been *un fait accompli*, it seems sufficiently simple, but in its inception it involved much controversy and debate which was at times tinged with acrimony

After the close of the Civil War, a great mass of insane pauperism seemed to become suddenly a public burden This incubus had been growing all along, but the people did not become aware of it until after the war and its all-absorbing issues had been disposed of Then the necessity for asylums became apparent, and every state in the Union, in its turn, found itself engaged in a struggle with this unwelcome and ever increasing burden In the several states one asylum after another was provided, but in nearly every instance, long before the doors were open, more than enough hapless defectives had accumulated in the almshouses and jails of the state to fill it to its utmost capacity A grim struggle with this increasing mass of human driftwood has been constantly in progress up to the present time The struggle seems absurdly unequal, for the forces of the state continually lag behind, balking at the enormous expenditures involved The situation may be likened to a "forlorn hope" assailing an inaccessible height It might be compared to the cutting of the Gaillard channel through the Culebra Mountain on the Isthmus of Panama each time when a new opening has been cleared, another inert mass slowly accumulates, obstructing the path of progress Vast treasure has gone into this great engineering enterprise, but the millions which have been poured into it are insignificant compared with the sums[1] which have been and will be expended in the conflict which civilization wages with the masses of defectives — its useless by-products, useless except as a test of the humanity and efficiency of our civilization We cannot doubt the ultimate victory of soundness and reason over disease and disorder, though at times conscious of anxiety and even alarm over the issue

---

* This article is a revision of the writer's history of Kankakee, one of the forthcoming series of histories of 'The Institutional Care of the Insane in the United States and Canada" to be published this year by the American Medico Psychological Association, under the editorship of Dr Henry M Hurd Volume I has already appeared from the Johns Hopkins Press

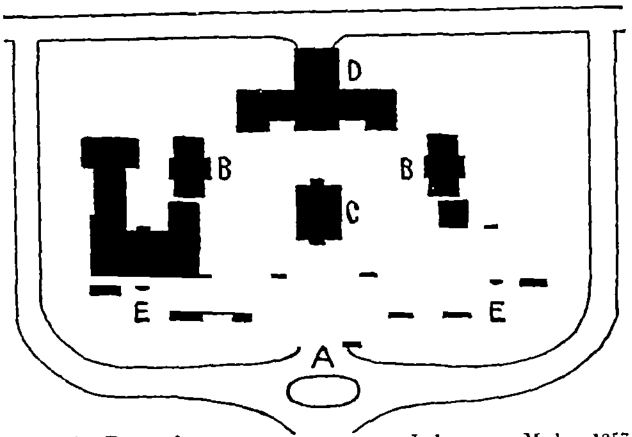

Fig 1 —Type of congregate institution Kalamazoo Mich 1857 scale, 100 feet equal 1 inch *A* administration *B B* infirmary *C* chapel *D* service buildings *E E* wards.

The institutions for the insane constructed in the United States prior to 1880 were always practically of one type, a massive, many-storied building with dominant central structure and wings extending far to right and left in sections and cross-sections wherein were gathered the hundreds of these incapables who fell to the grudging care of the state This "central building with wings" was accepted as a sole and universal model up to the last quarter of the nineteenth century Whenever and wherever a new insane hospital was wanted, it seemed to be a matter of course that an abject copy would be made of some one or another of the state hospitals already existing This type of building, the congregate hospital, apparently first modeled after a medieval monastery, and later, though improved from time to time in many details, still in arrangement and design retaining an institutional rather than a houselike or homelike character, remained the example to be followed under all circumstances It reached its highest development in the so-called 'Kirkbride" plan, named after the late eminent Dr Thomas Kirkbride of the Pennsylvania Hospital This uniformity of building seemed to imply uniformity in condition of the inmates, and evidently they "all looked alike" to the legislative eye All were considered dangerous, their principal need being confinement in a strong, secure building It was long before the idea entered the minds of the statesmen, who controlled the appropriations, that the insane were possessed of many human attributes, that the dangerous ones were the rare exceptions, and that dangerous or vicious conditions were often due to the evil environment provided by the state itself

Figures 1 and 2 show the two types of buildings As provision for the insane was more and more demanded, the efficiency and appropriateness of the congregate style of building came more and more into question The questioners were not the people identified with institutions, but, as is so often the case, outsiders were the critics One criticism of the prevailing style of building was its cost It required a minimum of a thousand dollars, and in some institutions three or four thousand dollars had been expended for every patient accommodated — enough to provide a house and lot for an ordinary citizen Other criticisms began to be heard It was claimed that a "sad idleness" instead of employment and diversion which would be both practicable and beneficial prevailed, and also that an unnecessary amount of mechanical restraint and confinement was used Visitors to institutions in other countries brought back reports of large industries, "open doors," abolishment of mechanical restraint and a more homelike atmosphere, especially was the colony for the insane at Gheel, Belgium, brought up as an example, in which an insane population of over 2,000 was mostly quartered in the homes of the peasantry All these discussions led to advocacy on the part of the public of "cottages" rather than "caravansaries" for the insane At the same time, those identified with the institutions maintained a strict adherence to traditional lines The advocacy of the so-called "cottage system" was "unorthodox," "impracticable," "theoretical" Discussion went on for years, and while changes were advocated from the outside, all was complacency within The ancient monastic structure was well intrenched, and the assaults of the reformers made little impression

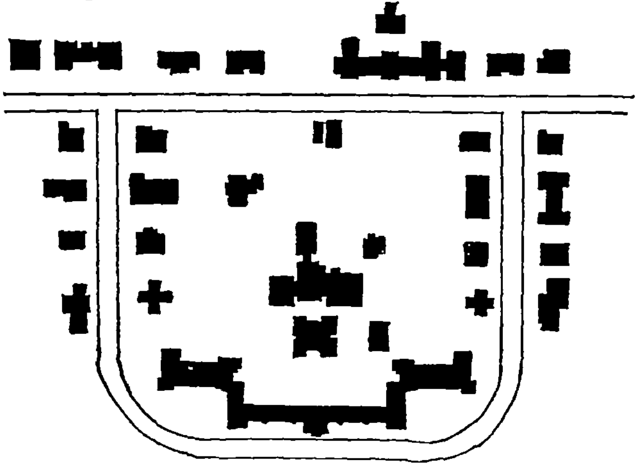

Fig 2 —Type of segregate institution Kankakee State Hospital 1880-1890 scale 500 feet equal 1 inch village plan first departure from congregate type The small building in the congregate style was retained in avoidance of too radical a change.

In the meantime, the demands for additional institutions had to be met, and various expedients were discussed The policy of separate and cheaper establishments for incurable cases was frequently proposed, and although this policy was ultimately discredited, yet in a notable instance it was adopted The Willard Asylum for Chronic Insane was established at Ovid, N Y This institution developed rapidly, reaching in the end a capacity of more than 2,000 inmates It was at first constructed in the well known congregate style, but a step in advance was secured in diminishing the cost of construction Under the admirable management of Dr John B Chapin, these buildings were constructed at an expense per capita of about $500 — less than half the amount that had previously been considered necessary

---

[1] For the support of 187 454 insane patients in public institutions of the United States the sum of $32 804 450 was expended in 1910 and each successive year shows an increase in the number of patients and in the expenditures involved (the latest available census figures)

Turning now to the inception of the hospital at Kankakee, we note that the Board of State Commissioners of Public Charities of Illinois, and especially Mr Wines, its secretary, had studied the question of buildings for the insane This board had pondered over these problems from its first assumption of office in 1869 Its members were aware of the criticisms which were rife in the community, and they had invited, by correspondence and conference, expressions from many men of expertness and experience in this field In that first year (1869) a meeting for discussion of this subject occurred at Chicago, at which Dr Andrew McFarland, then superintendent of the state hospital at Jacksonville, Ill, said

> The present system of architectural construction adapts the entire institution to the demands of its smallest and worst class, while for the great majority all these appliances are utterly unnecessary We need more of the element of home life I would not abolish the old form of institution The two systems may exist side by side I would have the central hospital in the foreground At a little distance I would have a group not of cottages, they should be houses of two stories in height Under this system facility of extension would be great Classification would be more complete

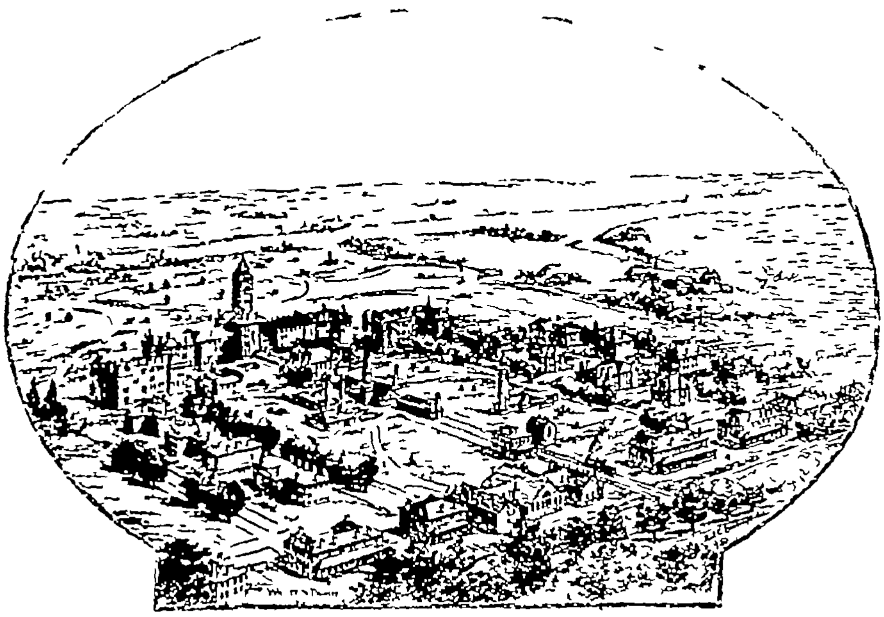

Fig 3 —Bird's eye view of Illinois Eastern Hospital for the Insane, Kankakee as it appeared in 1887, with a capacity of 1 600 patients The material of all buildings is either stone or brick, and the main building is fireproof throughout The total cost of the institution, which was begun in 1878, to 1887, for every expenditure except running expense, amounted to an average for each patient of $754 50 The average cost per patient on construction account alone (excluding cost of furniture, land, etc) was $590 18, cost of cottages under $500

At a later date, in the report of the state board for 1892, referring to the foregoing paragraph, Mr Wines, in stating the case for detached construction, said

> To Dr McFarland, therefore, more than to any other man, belongs the credit of planting the germ which has developed into the hospital at Kankakee His words passed unnoticed at the time, but they made a deep impression upon the state board, and especially upon its secretary, Mr Wines, in whose brain they ultimately took practical shape

The opinion arrived at by Mr Wines as a principle for development of future institutions was thus expressed

> The classification demanded (for the insane as a whole) was not in separate wards of one building nor in separate institutions (for acute and chronic), but in separate or detached buildings for the care of both acute and chronic cases in a single institution, under a single head

In noting the further steps in the genesis of detached construction, the fact is to be emphasized that when the appropriation was made for the new institution at Kankakee in 1877, the law was so worded as to make it *obligatory* for the trustees of the new institution to secure the approval of the board of charities to any plan they might adopt This practically made Mr Wines, the secretary of the board of commissioners of public charities, arbiter of the building plans, and here, for fuller elucidation, a few words must be given to Mr Wines, as he was a determining factor in the change of type in buildings for the insane

Frederick Howard Wines, formerly a Presbyterian clergyman at the state capital, and previously, during the Civil War, a chaplain in a Missouri regiment on the Union side, had become secretary of the state board of commissioners of public charities at the request of Governor John M Palmer It was a case of the "office seeking the man " Mr Wines was a brilliant writer and speaker, a man of broad sympathies and humanitarian motives He was also possessed of a grasp of economic principles and administrative details unusual for a clergyman Having familiarized himself with the subject of further provision for the insane, he had become an advocate of greater freedom and elasticity in constructive and administrative matters In 1878 he had been delegated to attend the world's prison congress at Stockholm Thus, while in Europe he had been able to study institutions and had become convinced of the practicability of the detached wards He submitted to the legislature on his return a report which resulted in the first appropriation for detached buildings at Kankakee, and the sum of $30,000 was appropriated for "cottages" to accommodate there 100 patients in three separate buildings Thus legislative approval was given for the first time to the detached ward idea

There was even yet a certain measure of apprehension in the mind of Mr Wines, as is shown by the following language in his report for 1882

> The foundation of this experiment was laid in fear and trembling The "cottage-system" had been a topic of discussion for many years, but the sentiment of the medical profession engaged in the care of the insane was adverse to it

The tradition of the congregate style of building had been so strong that in 1877 the board of trustees of the Kankakee Hospital in a joint conference with the board of public charities had decided that the first building erected must be the stereotyped central building with wings The board was unwilling to take the chance of so radical a departure from long usage as would be involved in total detachment Thus the leading strings of custom prevented progress at first, but the successive additions, in 1881, of three buildings for 100

[illegible] Page 119

patients, in 1883 of ten buildings for 1,000 patients, and in 1885 and 1887 of further extensions were all in the detached style, so that in 1893, more than 1,600 patients were domesticated under the village or cottage plan of construction,[3] and the successful working of these wards through all the subsequent years vindicated the claims that their originators had made for them

NONPARTISAN CONTROL

It is worthy of note here that the unusual conditions as to party control prevailing in the legislature at the time the institution was organized led to the appointment by the governor of a "nonpartisan" board of trustees, with two Republicans and one Democrat on this board of three members In the light of subsequent events, this feature may be regarded as fortunate, since partly in consequence of the minority representation and partly by reason of the disposition of all three members of the board to ignore partisan politics and to hold the superintendent alone responsible, civil service principles were consistently maintained during the fourteen years' service of the first superintendent[4] This fact had an important bearing on the development of the institution, as it enabled the administration to be free from all political interference

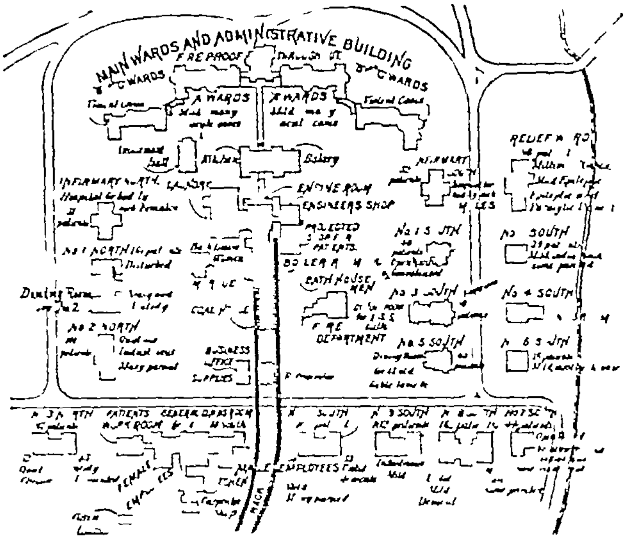

Fig 4—Ground plan of Illinois Eastern Hospital for the Insane Kankakee.

REDUCTION IN COST

The cost of detached wards at Kankakee did not exceed $500 per capita Up to the time when these buildings were erected, the congregate buildings universally in use had cost a minimum of $1,000 per capita A reduction in cost of about 50 per cent was thus effected, so that the amount formerly necessary for one patient would now provide for two This was better than "two blades of grass where one grew before"

INCREASE OF INDUSTRY

The percentage of patients employed rose from 42 per cent in the first biennial period to 57 per cent in 1888, 68 per cent in 1890, and 73 per cent in the last period of my superintendency (1892) Space will not admit of details concerning the great variety of trades and handicrafts which were introduced[5]

TRAINING SCHOOL FOR ATTENDANTS

In 1886 a training school for attendants was organized At that time there were but four schools in existence in institutions for the insane in the United States Up to March 31, 1893, 130 attendants had graduated, sixty-four men and sixty-six women Sixty were still in the employ of the hospital Eleven men and six women graduates were also employed in other capacities, having been promoted for merit[6]

DR ADOLF MEYER

An interesting fact in the history of Kankakee is the service there of Dr Adolf Meyer as pathologist from 1893 to 1895 Dr Meyer began at Kankakee a distinguished career, culminating in the professorship of psychiatry at the Johns Hopkins Medical School and the directorship of the Henry Phipps Psychiatric Clinic He secured during 1893 the purchase from the German government exhibit at Chicago of valuable apparatus He inaugurated staff meetings and a course of instruction for the medical staff, also greatly improved the case-taking system

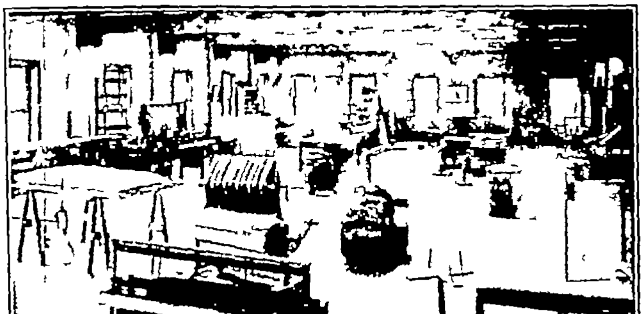

Fig. 5—Interior of men's workshop

---

[3] As showing the somewhat far reaching influence of the new departure at Kankakee the following facts may be noted The governors of Ohio and Indiana accompanied by a state commission and an architect or engineer each visited and inspected the detached wards at Kankakee in 1883 Later the institutions at Toledo (capacity 1 000) at Logansport (capacity 380) and at Richmond (capacity 400) all on the detached ward plan were constructed North Dakota employed Major Willett architect at Kankakee and in 1885 had 160 patients in three detached wards New York constructed a new hospital at Ogdensburg built in detached blocks in 1890 capacity when complete 1,500 patients. Ontario at Mimico near Toronto in 1890 had 240 patients in detached wards. New York City in 1889 had 360 patients in detached wards at Central Islip Any one interested in the views on building plans held at that period can find documents and discussions in the files of the American Journal of Insanity and in the 'Propositions and Resolutions collected and published in 1876 by the Association of Superintendents also the reports of the Board of Public Charities of New York Massachusetts, Pennsylvania and Illinois (the only state boards of charities in existence up to 1869) The report for 1884 of the Illinois Board of Public Charities, Chapter III p 65 has a very full summary of the subject from the pen of Secretary Wines.

[4] Having been the first superintendent the writer well remembers one of his first official acts—the securing of a carpenter After thorough inquiry the man found by all odds best qualified was selected but when later the appointment became known to the local boss of the political machine a period of consternation ensued and the superintendent discovered that he had appointed a Democrat instead of a Republican carpenter In local political circles this was felt to be a serious blunder There was no interference with the appointment however and that same good craftsman remained in full exercise of his functions until fourteen years later when a new governor (Altgeld) decapitated all the boards of trustees in order to secure at each institution a superintendent who would do his bidding

[5] In addition to all the usual domestic and farm and garden employments the following industries were regularly in use (see biennial report for 1890 p 20) broom making chair caning upholstering scroll sawing rug and mat making, rag carpet weaving tailoring shoe and slipper making and repairing, harness making tin smithing wall painting and decorating the making of paper flowers basket making knitting (all socks and stockings used), printing engraving and picture framing

[6] The training school fell into disuse for many years owing to political changes but has been reestablished in all the institutions in late years.

LESSENING RESTRAINT AND INCREASING PRIVILEGES

Mechanical restraint (the use of straight jacket, muffs, etc) in that day, as always considered an evil, was apt to be treated as a necessary evil and more or less a matter of course The policy adopted at Kankakee resulted in making it a rare exception No apparatus was kept in the ward If used it was applied only by the physician personally after an investigation as to its need This alone made restraint a rarity A report and record were made and kept on file of all cases of restraint or seclusion that occurred

To introduce more homelike atmosphere and soften the rigor of confinement and restraint was an especial object kept in view The following notes, taken from the "Illinois Institution Quarterlies" of 1914 indicate the progress made, and show that it has been continued in late years

> "At this time there are 1,000 paroled patients There are twelve open" cottages, whose doors are never locked and whose windows are not barred or screened Women attendants on male wards have been increased in number, ten wards have been put in charge of female nurses Every screened door has been taken off No patient's door has been locked at night In two months there has been no seclusion and only one case of "mechanical restraint" among an average of over 2,000 patients"

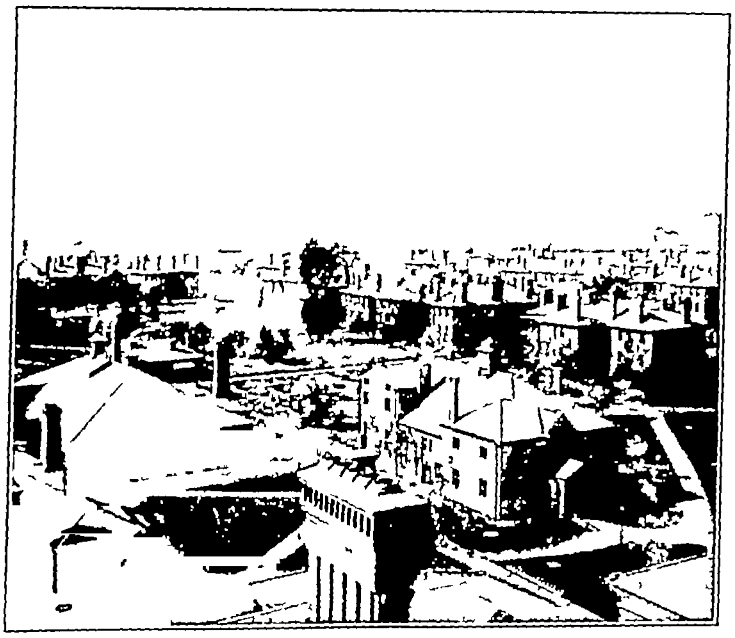

Fig 6 —View looking northwest.

These conditions were attained under the superintendency of Dr Sidney Wilgus

As the hospital at Kankakee was avowedly a departure from methods previously prevailing in architectural construction, and was administered with the purpose of putting to the test certain progressive ideas, the foregoing facts and statements are given

CONCLUSION

In closing we may ask the following question Was the more domestic style of construction, the so-called "cottage" or "detached ward," successful, and did it win general approval?

This question is answered by results immediate and remote so well known as to require only the briefest statement The more simple, segregated and less expensive style of architecture employed in the detached buildings at Kankakee as a substitute for the many storied congregate central building with wings (previously considered necessary) was given immediate recognition in many states, as shown above, and is accepted today as a matter of course

It may be said that *freedom* in construction rather than any stereotyped form of building resulted from the experience at Kankakee The change in constructive ideas would have come in any event, but was helped quite decisively by the experience obtained at Kankakee The fact was established that efficient care is the first essential, and is more important than any particular type of building

The reader is now, I hope, in a position to form his own opinion concerning the institution at Kankakee

In closing my account, as the person through whom the institution's plans and progress were carried out in its formative years, I desire to pay a tribute of honor to the memory of Frederick Howard Wines His ability and force of character were the originating and sustaining power in inception of "segregated" construction at Kankakee, as opposed to the "congregate" style previously prevailing His ideas, ably and eloquently presented, were the source of much that was new and valuable in the evolution of greater freedom, adaptability, intelligence and efficiency in constructing and organizing institutions for the insane in the United States

---

THE ETIOLOGY OF IRITIS*

ERNEST E IRONS, MD

AND

E V L BROWN, MD

CHICAGO

This study was undertaken primarily to determine the causes of "rheumatic" iritis, but in the absence of any clear distinguishing features of this form apart from etiology, we have included all cases of nontraumatic iritis,[1] and after examining each patient as completely as possible, have grouped them in accordance with the causes discovered in each

This report does not assume to be a complete survey of the causes of iritis, but is rather a recital of the infections which we found and of the evidence for and against the etiologic relation of each to the iritis The final conclusion as to the relative importance of each cause must be left to future studies

One hundred patients (forty-seven private and fifty-three clinical) have been thus studied[2] Careful attention was given to the history, and a complete physical examination was made to detect the presence of syphilis, tuberculosis, gonococcal infection, and infections of teeth, tonsils, sinuses, prostate, pelvis or other structures which might give rise to lesions in joints or eyes Laboratory examinations included Wassermann tests (ninety-eight patients) controlled by two laboratories, complement-fixation tests for gonococcal infection, roentgenograms of teeth and sinuses, and of the lungs when there was any question of pulmonary disease, and cultures of pus from tonsils, sinuses, prostate and other infected tissues Tuberculin tests, 1, 3, 5 and 10 mg being used, were made in suitable cases

---

* From the Memorial Institute for Infectious Diseases, and the Presbyterian and Cook County Hospitals

* Read at the Fifty Second Annual Meeting of the American Ophthalmological Society, Washington, D C, May 9, 1916

[1] The eye condition encountered has been for the most part "plastic" iritis Certain cases showed a more marked involvement of the ciliary body or anterior choroidea, and the diagnosis was accordingly modified to "serous" cyclitis or to iridochoroiditis All cases were studied during an active stage of iritis No cases of sympathetic iritis or iritis following wounds, operations or ulcers have been included We have not encountered any cases of fulminating suppurative panophthalmitis during the period of this study

[2] We are indebted to Drs Wescott Pusey, Wilder, Darling Beard and Blue for the privilege of using the notes of cases referred to one of us (E E I) for study We are also indebted to a number of our colleagues, whose cooperation in painstaking and laborious clinical and laboratory examinations has added much to the completeness and accuracy of our study Among others, we acknowledge the valuable assistance of Drs Ormsby, Harris McEwen and Stillians in the diagnosis of certain cases of syphilis, Drs Shambaugh Friedberg, Boot, Beck and Sonnenschein in examinations of the nose throat and sinuses, Drs Gilmer, Moorehead, Potts, Puterbaugh and McGuire for advice in and treatment of dental conditions, Drs Potter and Blaine for many roentgenographic studies of teeth and sinuses, and Drs Nicoll Bissell and Moody for extensive serologic studies

After a complete survey of the patient, appropriate measures were taken to remove all infections so far as possible From the course of the iritis following these procedures, we obtained valuable evidence confirmatory of the etiologic diagnosis In patients in whom we found but one source of infection, removal of which was followed by immediate improvement of a previously intractable iritis, no special difficulty was experienced in drawing reasonably safe conclusions as to the relation of cause and effect

We found two or more infections associated in a surprisingly large number of patients In many of these the reason of the association was obvious, thus, infections of tonsils, sinuses and teeth, or syphilis and gonococcal infection were often found together In other instances, there was no apparent direct relation between two infections, such as syphilitic iritis from secondary syphilis, associated with a latent alveolar abscess

THE CAUSES OF IRITIS IN ONE HUNDRED CASES

Infections	Alone	With Other Infections	Total	Coincident Infections: Syphilis	Gonorrhea	Tuberculosis	Dental	Tonsil	Sinus	Genito Urinary
Syphilis	10	13	23		8	5	5	1	1	
Gonococcal infection	7	2	9				1	1		
Tuberculosis	8		8							
Dental infection	7	11	18	2	2	2		7	1	
Tonsillar infection	7	9	16	1	3	2	7			
Sinus infection..	1	2	3				1	1		
Genito-urinary (nonvenereal)	3		3							
Other infections	2		2				1			
No cause found	1		1							
Combined infections			17	8	9	7	8	13	5	1
			100							

By a careful weighing of all the evidence, we were able to determine in most cases which infection was probably responsible for the disease of the eye, but sometimes the available evidence was insufficient, and we have placed such cases in a "combined" group Some of these patients suffered from several infections Syphilis, active tuberculosis, gonococcal infection and alveolar abscess were repeatedly found in the same individual

The accompanying table summarizes (1) the number of times each infection was found in direct etiologic relation with the iritis, and (2) the coincident infections found

SYPHILIS

The relation of syphilis to iritis affords one of the most interesting studies in this series

The history of infection, and the evidence of past and present infection, were carefully investigated in each case In ninety-eight cases, Wassermann tests, usually controlled by two laboratories, and in doubtful cases repeated two and three times, were made In the two cases in which this test was not made, there was no history or clinical evidence of syphilis, and the iritis in both was definitely ascertained to be due to other causes

In thirty-nine cases, syphilitic infection had occurred either recently or years before Of these cases, twenty-eight were dispensary and eleven private patients In twenty of the thirty-nine cases, the iritis was clearly syphilitic, of this twenty, thirteen showed other clinical evidence of active syphilis Of the seven in which other active syphilis was not apparent, the Wassermann reaction was positive in all The iritis was recurrent and had been previously observed in association with acute syphilis in four, a condyloma of the iris was observed in another, in two the diagnosis would have remained in doubt without the Wassermann test All seven recovered promptly on antisyphilitic treatment Three other cases of the thirty-nine probably were due to syphilis, judging from the prompt relief following antisyphilitic treatment, although other possible causes, such as active gonococcal or tonsillar infection, were also present

The remaining sixteen cases of the thirty-nine are of interest because they illustrate the obvious fact that a person infected with syphilis may also suffer from bacterial infections, which may be the real cause of secondary metastatic lesions We shall refer later to the influence of one infection in the body on other subsequent infections

Of the sixteen cases in which the iritis was not syphilitic, the grounds on which syphilis was excluded as the cause varied In none were there signs of active syphilis In five the time of infection was remote, seven, twenty-two, twenty-five, twenty-seven and forty-five years previous, and the Wassermann reaction negative In all, there were other causes present, following the removal or appropriate treatment of which, where this could be done, the iritis subsided without antisyphilitic treatment In several of these, the iritis had previously resisted antisyphilitic treatment in other hands Among the causes of the iritis in these cases were tonsillar, sinus and gonococcal infection with arthritis In three the iritis subsided at once after the drainage of alveolar abscesses In one case due to alveolar abscesses, the iritis appeared contemporaneously with extensive arthritis, while the patient was receiving mercury for syphilis of twenty years' standing Removal of the abscesses resulted in prompt cure of arthritis and iritis

The distribution of syphilitic iritis between the dispensary group and the private group of cases is of interest Of forty-seven private cases, syphilis was present in eleven, and was the cause of the iritis in six, while of fifty-three cases in the clinic, syphilis was present in twenty-eight, and was the cause of the iritis in seventeen The patients in the clinic at Cook County Hospital were in part referred to us as outpatients, and in part came from the wards of the county hospital, including the venereal ward The inclusion of several cases of syphilitic iritis from the venereal ward raises the proportion somewhat above what might be encountered in a hospital which does not receive patients with active syphilis We have been able to discover no other reasons for assuming that the figures given do not fairly represent the proportion of syphilitic iritis in a metropolitan clinic, so far as conclusions may be drawn from a limited number of cases

In unselected groups of cases syphilis is encountered more frequently in the wards of a charity hospital than in private practice, and in the latter also the disease is more likely to be efficiently treated, and the complications of untreated syphilis are therefore less frequent.

Out of 100 successive cases of iritis, there were only twenty-three in which syphilis was the cause of iritis, and sixteen others due to other causes in which syphilitic infection had occurred, making a total of thirty-nine patients in whom syphilis had to be seriously considered in the etiologic diagnosis. This leaves sixty-one cases in which a searching examination failed to reveal any evidence of past or present syphilitic infection, and in which, therefore, the iritis could not be reasonably thought to be due to syphilis.

So far as one may draw conclusions from this number of cases, it would seem that the widely accepted statement that 50 per cent. or more of iritis is due to syphilis may have to be revised. Certainly in the absence of other evidence of active syphilis in a patient with iritis, the assumption that the iritis is syphilitic is more likely to be wrong than right.

DENTAL INFECTION

Infections about the teeth occur in a large proportion of all persons, and care must be exercised in ascribing to such infections a causal rôle when they happen to be found in the subjects of iritis, or other metastatic lesions.

In this study we have not included peridental infections as possible causes unless they were closed processes, that is, apical infections (alveolar abscesses), demonstrated by roentgenograms and confirmed by the oral surgeon on extraction.

In certain cases of extensive pyorrhea, lateral abscesses occur, or the tissues may be deeply invaded with resulting metastatic lesions; but in the present series, such cases have not been encountered. In several cases, alveolar abscess was the only discoverable infectious process in the body, and the removal of the abscess was followed by prompt and permanent relief of the iritis.

Alveolar abscesses, or apical infections demonstrated by roentgenograms and confirmed by the oral surgeon, were found in forty-one patients (twenty-four clinical and seventeen private). In eighteen patients (ten private and eight clinical), we regarded the dental lesion as the source of the iritis. The evidence on which this conclusion was based varied in the several cases, but included such facts as the absence of other sources of infection and the prompt clearing of the eye on removal of the cause, or the association of the initial attack or recurrences of iritis with known dental infection; or, if other infectious processes were also present, the failure of treatment to relieve the iritis until the abscesses were discovered and removed.

In ten clinical and five private patients the iritis seemed to be clearly due to other causes, such as syphilis and tonsillar infection, and the dental infection relatively inactive so far as concerned the causation of metastatic lesions. Latent alveolar abscesses are often found in persons not suffering from iritis or other evident metastatic disease.

In the remaining nine patients (seven clinical and two private) the dental infection was associated with other infections, often two or more, including tonsillar, sinus, syphilitic or gonococcal, and we were unable to satisfy ourselves which infection was responsible for the disease of the eye. So far as possible, we tried to arrange the sequence of surgical and other treatment so that we could observe the effect of each procedure on the eye; but in a number of instances, considerations of expediency and the saving of vision made it necessary to proceed rapidly to the elimination of all possible causes of the iritis.

Cases of this type, in which the difficulty in assigning a cause for the iritis arose not from inability to find an infectious process but in deciding between several adequate causes, we have preferred to group under the heading of "combined infections," rather than to guess as to which of the infections was the exciting cause of the iritis. This group will be discussed later.

TONSILLAR INFECTION

Tonsillar infections appear to be as important an etiologic factor in iritis as in arthritis and other metastatic lesions. Under tonsillar infections, we have included deep infections of the tonsils, and intratonsillar and retrotonsillar abscesses, but have not included slight lesions such as small crypts containing "cheesy" material, unless accompanied by deeper infection. Superficial infections are not to be disregarded in the routine examination, however, for they often furnish a clue which leads to further investigation and the discovery of deeper hidden infection.

In some cases the history of previous tonsillar infections, the appearance of the tonsils, the enlargement of regional lymph nodes, and the associated arthritis and myositis point directly to the tonsils as the source of the iritis; but in other cases, careful and repeated search is required to discover the deep tonsillar abscess, the removal of which results in relief of the iritis.

The tonsil was clearly the source of infection in sixteen cases (twelve private and four clinical). In thirteen cases of the combined group, tonsillar infection was present with other infections; but, as in the case of dental infections, we were not able to determine whether tonsillar or dental infection was the immediate source of the iritis. It is of some interest to note that twelve of these thirteen combined cases were in the dispensary group, and if all the facts could be determined, it is probable that a number of these would fall in the tonsillar group, thus raising the proportion of tonsillar cases in the dispensary group from four clearly defined cases to a number more nearly corresponding to that in the private group (twelve cases), in which multiple infections were less numerous, and consequently an etiologic diagnosis more easily made.

In cases clearly due to other causes, tonsillar infection was found in several; in the syphilitic group, two; gonococcal, one; sinus, one, and dental seven. Tonsillar and dental infections are frequently found together, and the question may well be raised as to whether the dental infection may not have developed in previous months and years by the same mechanism as the iritis, by repeated infections from the tonsils. Cultures from tonsillar abscesses after tonsillectomy often showed hemolytic streptococci.

GONOCOCCAL INFECTION

Gonococcal infection was believed to be the cause of the iritis in nine patients, all male. In eight of these an active or recent, usually multiple, arthritis was present. In seven the iritis was recurrent and often associated with recurrent arthritis following exacerbations of urethritis. In one case the iritis occurred during an acute gonorrhea without arthritis. In another a recurrence of the iritis was noted during a period of fever, with arthritis, and the gonococcus was isolated from the blood. A positive gonococcal complement fixation test was obtained in six of seven cases in which it was made. Three of these patients came to one of us for advice as to arthritis, so that it is possible that the proportion of gonococcal iritis is slightly larger than would be the case in a second hundred cases in which this element of selection was not operative.

In seven of the nine patients, infections other than gonococcal were not found; in the other two, both recurrent, tonsillar or dental infections were found, but the recurrences were closely associated with exacerbations of urethritis and arthritis. It is, of course, conceivable that a urethritis with general infection and arthritis might so depress the resistance of a patient to other infections that a latent infection in the tonsil might give rise to an iritis; but such an assumption seemed hardly justified in the two cases under discussion. All evidence in each case must be considered, however, for the mere finding of a positive complement fixation test in the subject of gonorrhea does not indicate a gonococcal origin of the iritis any more than a positive general tuberculin test alone indicates that an iritis is tuberculous.

In cases due to other causes, gonococcal infection was present in thirteen: eight of the syphilitic group, two of the dental, and three of the tonsillar, all dispensary patients.

In the combined or undetermined group, evidence of active gonococcal infection was found in nine, of whom eight gave a positive complement fixation test. All nine patients were in the dispensary group. One or more attacks of multiple arthritis with recurrences of urethritis had occurred in several of these patients. In one patient who had contracted syphilis twenty-two years previously, the initial attack of iritis occurred four years later coincidently with arthritis and directly following urethritis. During the year preceding the present attack, the iritis had recurred coincidently with the appearance of tertiary syphilitic lesions of the leg and mouth. At the time of examination the syphilis had healed under treatment, but the iritis was still active, the Wassermann was negative, and gonococcus complement fixation positive. The mouth was extremely foul with extensive caries and gingivitis (apparently not mercurial), but no alveolar abscesses were found. A positive tuberculin reaction followed the injection of 1 mg. O. T., and later an acute attack of tonsillitis occurred. Here it seems reasonable to assume that the initial iritis may have been gonococcal, but the possibility of the active participation of one of the other coincident infections cannot be excluded.

Such cases as the foregoing illustrate the difficulty of evaluating the several possible causes of iritis in patients, especially of the dispensary group, in whom multiple infections are frequently found.

TUBERCULOSIS

In eight patients (three clinical and five private) the iritis appeared to be tuberculous. In seven the evidence seemed clear, and in one presumptive. In two of the seven, active clinical tuberculosis was present, and in five positive tuberculin reactions, together with other evidence of tuberculosis, such as changes in the lungs, were demonstrated by physical examination and roentgenoscopy. In two cases focal reactions in the eye repeatedly occurred following tuberculin tests; in interpreting these reactions, care was taken to avoid confusing them with the sudden exacerbations of inflammation which may occur spontaneously in iritis. In none of the seven was there any other discoverable focus of infection.

Evidence of the presence of tuberculosis, usually latent, was found also in five patients in whom the iritis was due to syphilis, in two each of the dental and tonsillar groups, and seven of the combined group, the latter all dispensary patients.

SINUS INFECTION

In three patients the iritis was considered due to infection from the sinuses. In several others, the sinuses were infected together with other structures such as tonsils and teeth, but it was not possible to determine whether one or another of the lesions was the immediate source of the iritis, and these cases were accordingly placed in the combined group. For practical purposes the importance to the patient lies in the recognition of the presence of infection, whether it is in one or more places, and its eradication.

Abnormalities in the several sinuses were discovered on routine clinical examination or by roentgenoscopy in nineteen cases, in ten of which active infection was demonstrated. In spite of able assistance, and the recent advances in roentgenographic and clinical diagnosis of sinus disease, we have experienced more difficulty in determining the presence or absence of infection in the sinuses than in any other region of the body.

OTHER INFECTIONS

In three cases, the iritis was associated with nonvenereal infections of the genito-urinary tract, including two of the prostate.

In one instance no adequate cause for the iritis was found.

Diabetes was present in three cases, but in each instance, infections were also present, in one, alveolar abscess; in one, tonsillar abscess, and in one, tuberculosis, syphilis and tonsillar infection.

Several cases came to us with a provisional diagnosis of "iritis from autointoxication." In none of these did we fail to find active infectious processes, such as tonsillar or alveolar abscess, and the previously resistant iritis subsided on relief of the infection without measures specially directed toward the treatment of the supposed "gastro-intestinal autointoxication."

When anemia, weakness, anorexia, achylia, diarrhea or constipation occur in the course of an acute infectious disease, or in certain chronic but clinically evident infections, we recognize that they are the results of disturbance of the functions of the body arising from the infection; but when they are associated with unrecognized infections, together with metastatic lesions of the joints or eyes, we may be tempted to correlate the gastro-intestinal disturbance with the arthritis or iritis, and overlook their common cause. There is no question as to the importance of the regulation of diet, of the correction of constipation, and of all other measures which will improve nutrition and increase bodily resistance to infection; but even these important procedures should not be allowed to supplant or interfere with the search for infectious foci and their eradication.

COMBINED INFECTIONS

There were seventeen patients in whom several infections were present, or in whom there were several foci harboring the same or different infections in such combination that we could not with certainty determine which infection had given rise to the iritis These cases have already been referred to in discussing the incidence of the several types of infection

The patients belonged largely to the dispensary group, and careless habits of life and the physical handicap imposed by the disability arising from some one infection, such, for example, as gonococcal arthritis or pulmonary tuberculosis, no doubt contributed to the lessening of resistance and made the sufferer more susceptible to subsequent infections The unfavorable action, as regards the host, of one infection on another was probably also a factor in producing the large number of infections and their complications in this group

But even in this unfavorable residue, the results of treatment directed toward the elimination of the infections were remarkably good, and we had the satisfaction of seeing many hitherto stubborn cases of iritis relieved

In twelve of the seventeen, recovery followed the removal of infectious processes In two cases satisfactory results were not obtained despite months of treatment, secondary glaucoma was present in both

In two we were unable to complete the eradication of infections, and one patient is improving slowly under tuberculin

THE MECHANISM OF THE PRODUCTION OF IRITIS

Focal infections are very frequent, and yet many persons do not suffer from iritis or other metastatic lesions Sepsis, streptococcal or pneumococcal, is also frequent, but metastatic lesions of the eye relatively rare Given an alveolar or tonsillar abscess, what are the causes which lead to the production of iritis or arthritis in one person and not in another, at one time and not at another? An adequate answer to this question requires a more complete knowledge of the mechanism of immunity than we now possess, and certainly a discussion of what is already known would require more space than is at our disposal A consideration of some of the factors involved is possible, however

Iritis can be produced in animals by intravenous injection of bacteria, as shown by Stock and others

Bacteria reach the eye by the circulating blood, and can be recovered from the eyes of animals in which iritis has been experimentally produced

In some recent experiments we have produced iritis in rabbits by intravenous injection of the streptococcus, *B mucosus capsulatus* (Friedländer), *B pyocyaneus,* and the gonococcus Usually, however, in order to accomplish this, large doses must be given, so that a condition of sepsis is created, and then only in occasional animals is iritis produced Certain of these animals recover, and the lesion of the eye heals

If one of each of a series of rabbits is injured by intra-ocular injection of minute amounts of dead bacteria, and then after the eyes have healed and all active inflammation has disappeared, an intravenous injection of living bacteria is given, there follows an inflammation of a larger proportion of the injured eyes than of the control eyes By this procedure we have produced ocular inflammations by the injection of staphylococci as well as streptococci Such experiments bear directly on the problem of recurrences of iritis

In addition to the factors of sepsis, fortuitous embolism, and previous trauma of the eye, changes in the organisms themselves must be considered in a study of the causes which determine the occurrence of lesions of the eye In a case of streptococcal infection of the tear sac which had presumably given rise to iritis, we were able to produce iritis in rabbits by injection of streptococci when first isolated from the patient[3] Later the same cultures and other cultures obtained at subsequent dates from the patient failed entirely to produce lesions of the eye We were not able to make out any changes in morphology or cultural reactions coincident with the change in localization with respect to the tissues of the eye

From our clinical study and from our experiments thus far, it would appear that not one but several factors are concerned in the production of iritis, among which may be noted the presence of a focus of infection in which bacteria may live and multiply, partially protected from the resisting forces of the host, the periodic entrance into the blood stream of these organisms and their lodgment in the eye, either by reason of their great number as in sepsis, or by fortuitous embolism, changes in the eye itself, either in vascular anastomoses, or in susceptibility of the ocular tissues owing to previous injury, and finally changes in the organism itself, whereby it becomes better able for a time to maintain itself in the tissues of the eye Such adaptations on the part of the organism do not necessarily imply any demonstrable change in its morphology or cultural reactions

CHYLOTHORAX, CHYLOUS ASCITES AND LYMPHOSARCOMA

REPORT OF CASE

HENRY ENOS TULEY, MD
Professor of Pediatrics, and Dean, University of Louisville, Medical Department
AND
STUART GRAVES, MD
Professor of Pathology and Bacteriology, University of Louisville Medical Department
LOUISVILLE, KY

Chylothorax is a comparatively rare disease The case herein reported was typical and was fortunately followed by a postmortem examination

REPORT OF CASE

Clinical History (by Dr Tuley) —Mrs M, aged 58, married thirty-six years, with two children living, had five brothers and sisters, of whom one died of "brain fever," one of typhoid fever and one of pneumonia, those living being in good health The menopause occurred seven years ago, without complications The patient has always been robust, the normal weight being about 200 pounds For several months she complained of pain in the scapular regions of both sides, and could not lie on her back For a year she has had pain and fulness in the epigastrium after eating She had had an acute attack of tonsillitis in September, 1915, being then attended by Dr W F Boggess Recovery from this was uneventful

I first saw the patient, Oct 4, 1915, for an attack of dyspnea, the cause of which seemed apparent as the chest was full of sonorous and sibilant rales, and the breathing was typical of asthma She was given a calomel purge, kept quiet and improved, but on the 21st was seen by Dr Frazier in my absence from the city, for a recurrence of the dyspnea In view of the condition of the throat, one tonsil having a thin patch on it, and a severe pyorrhea alveolaris, it was deemed advisable to administer some autogenous vaccines, which was done, during the next ten days, with a cessation of the adventitious sounds, but no improvement in the dyspnea. November 1, a careful examination was made of the thorax, and the presence of fluid diagnosed in the left pleural cavity A peculiar feature of the chest findings at this time was the presence of bronchial breathing over the entire left lung, anterior and posterior, with intense flatness over the left base At this time she was seen by Dr Weidner, and the diagnosis of pleural effusion confirmed November 2 a thoracentesis was done through the eighth interspace, and 3 pints of thin milky white fluid were withdrawn The appearance was that of pus, but an examination showed it to be free of cells and to be a sterile chylous fluid The relief from the dyspnea was almost immediate, there being but little cough following the aspiration

November 8, with a return of the dyspnea corroborated by chest findings, the left pleural cavity was again tapped and 3 pints of chyle removed

November 14 3½ pints were withdrawn, November 24, 4 pints, December 2, 4 pints, December 6 4 pints, December 30 3½ pints were withdrawn from the right pleural cavity, February 6, 4 pints of serous fluid from the right and 2 pints from the left, February 15, 2 pints of chyle from the right and 1½ pints from the left, February 20, 3 pints from the right, February 29 3 pints, March 8, 4 pints, March 13, 3 pints, March 18, 2¾ pints, and March 26, 3 pints, all from the right The total quantity of chylous fluid removed from this patient's chest was 48¼ pints

December 20, a spot developed on the right tonsil ¾ by 2 inches in size The exudate was thick dirty white very tenacious, leaving a bleeding surface when removed and looked very much like the membrane of diphtheria At this time the patient was seen by Dr A O Pfingst Bacteriologic examination was negative for the Klebs-Löffler bacillus but the typical spirilla and organisms of Vincent's angina were found associated with all varieties of pus-producing organisms At this time a chain of enlarged glands was found in the right neck which remained large up to the time of her death

The patient failed rapidly from the middle of March Emaciation was progressive and sedatives were required constantly to quiet the restlessness though no great pain was complained of Marked edema of the lower extremities developed and a chylous ascites was present during the last two weeks A small quantity of chylous fluid was aspirated from the peritoneal cavity a few days before she died Death occurred quietly at 5 a m., April 8 1916

The chemical analysis of the thoracic fluid (Table 1) follows closely that given by Wells[1]

Urinalysis, November 23, revealed specific gravity, 1 018, acid, no sugar, no albumin, triple phosphates, crystals, few leukocytes, hyaline and granular casts

October 5, the specific gravity was 1 012, and the urine was negative except for crystals of ammonia, urates and a few leukocytes

Dr Bayless' report of the Roentgen-ray examination, December 3, showed the right side normal with a movement of 2 inches of the right diaphragm On the left side from below the third rib in front, it was dark, above the third rib the lung was clear but somewhat emphysematous The area was so dark that no details of the lung could be made out It might have been a thickened pleura with fluid or some new growth The heart was in the normal position The posterior mediastinum above the third rib was clear Below it was dark, but evidently from the same condition which caused the dark area in the left chest

The Wassermann reaction on the blood taken December 1 was negative and the cultures made from the fluid from the left pleural cavity were negative A few lymphocytes were noticed

A careful examination of the blood between the hours of 9 p m and midnight was made by Dr Moore without finding any evidence of filariae

REVIEW OF LITERATURE

The literature of chylothorax is very meager, though there are a number of references to chylous ascites

The most complete report which has been accessible is by Sale,[2] who reported one case and reviewed the literature on the subject complete to the year 1899 He found a record of forty-one cases reported in the past 260 years

The etiology of this condition is of interest, and the causes given by Sale in the recital of these reported cases are new growths or tuberculous lymph nodes, 9, thrombosis of the left subclavian vein, 4, secondary growths in the duct itself, 9, perforating lymphangitis, 2, aneurysm of the duct itself, 2, and 1 each of thrombosis of the duct, operation for removal of lymph glands of the neck, mitral disease, filariae, and inflammatory thickening of the mesentery

Warthin[3] has a very complete description of the various anomalies and pathologic conditions of the thoracic duct which may result in escape of the chyle

He describes thrombosis of the chylous duct as one of the most frequent complications resulting in chylothorax, and its etiology is given as hemorrhage into the duct, inflammation of its wall, trauma, tuberculosis, metastasis of malignant tumors, infection, filariae, pressure of neighboring tumors, aneurysms, anomalous vessels, exostoses of the vertebra, obliteration of the left subclavian vein, etc

The symptomatology of thoracic duct thrombosis is purely one of obstruction so far as its distinctive features are concerned Chylous ascites alone or combined with chylothorax or chyluria would point to such an obstruction Obscure abdominal pains, intestinal disturbances, edema or elephantiasis of the lower extremities or external genitals may occur as features of the clinical picture

In all cases in which the collateral circulation is inadequate there results a chyle stasis with dilatation of the duct and radicals The chyle may escape from the distended vessels by transudation or rupture, and may infiltrate the tissues or collect in the serous cavities, giving rise to a chylothorax, chylopericardium or a chylous ascites

[3] Warthin in Osler's Modern Medicine.

Dock[4] reports a case of chylous ascites and chylothorax in which there was a lymphosarcoma with lymphocythemic blood, though the white cells were not greatly increased.

From the few reports found in the literature it would seem that secondary sarcoma of the testis, lymphocytoma of the mesentery, osteosarcoma or chondrosarcoma of the pelvic bones and primary endothelioma of the peritoneum are the most frequent primary lesions found.

NECROPSY

The postmortem report is abbreviated to those conditions having to do with the chylothorax.

Examination (made April 8, 1916, three hours after death, at the home of the patient by Dr. Graves assisted by Dr. Moore).—The body was poorly nourished. There was marked edema in the lower legs and thighs.

Peritoneal Cavity. Superficial fat was 3 cm. thick and bright yellow. About 500 c.c. of thin, milky fluid was in the cavity. Small fatty globules floated on the surface of this fluid. The peritoneum was everywhere smooth and glistening. The liver reached 15 cm. below the base of the xiphoid cartilage, and 5 cm. below the costal margin in the right midclavicular line. Diaphragm. Left, sixth rib, right fifth interspace. The appendix was retrocecal, free, pale, curled on itself, lying toward the pelvis. The mesenteric nodes were enlarged. The foramen of Winslow was patent, but the lesser sac was encroached on by a moderately firm, nodular, retroperitoneal mass. The lymphoid tissue is described later.

Pleural Cavities. The right lung was pushed upward by a collection of milky fluid which filled the lower half of the right cavity so that the lower border of the organ lay opposite the fourth rib anteriorly and the sixth rib laterally. This fluid was similar to that in the peritoneal cavity except that some of it soon after the admission of air appeared clotted. Firm, fibrous adhesions bound the lung to the wall over the greater portion of its surface except the inner aspect of the apex. Between it and the wall there was no fluid or other obvious abnormality. The left pleural space was entirely obliterated with dense, fibrous adhesions except over an area about the size of the palm between the infero-lateral aspect of the lower lobe and the chest wall, where there was a shallow pocket filled with the same chylous fluid.

Pericardial Cavity. This contained about 15 c.c. of clear serous fluid.

Lungs. Both organs were compressed and covered with fibrous tags. Crepitation was much diminished. The organs were doughy and pitted on pressure. On section they were dark red and did not present a normal spongy appearance.

Spleen. This organ was enlarged, was firmer than normal, had a pale gray capsule, measured 6 by 9 by 18 cm. and, on section, presented a great many round or oval, fairly well circumscribed, raised, grayish, homogeneous nodules in dark red parenchyma. The largest deposit was about 25 mm. in diameter.

Pancreas. The head was involved in a tumor as described below. The tail was negative.

Tumor and Its Relations. The lymph nodes from the neck to the pelvis, especially those lying in the posterior mediastinal space and retroperitoneal, were involved in an apparently primary neoplasm which was growing around the structures in those regions but did not infiltrate any except the head of the pancreas. The cervical, axillary, supraclavicular and infraclavicular and bronchial nodes varied in size, the largest being about 2 cm. in greatest diameter, were encapsulated and moderately firm, and, on section, pale flesh color and homogeneous except the last, which were speckled with black. The posterior mediastinal nodes were much larger, reaching a maximum diameter of 4 cm., but were encapsulated and softer and paler on section. Below the level of the diaphragm the nodes seemed conglomerate in a mass larger than one's fist, and involved the head of the pancreas. On section this tissue was moist, pale, homogeneous and typically like fish flesh, while scattered in it could be seen lobules of pancreatic tissue. The lymph nodes along the lesser curvature of the stomach, in the gastrohepatic omentum and retroperitoneal along the aorta were enlarged, those in the gastrohepatic omentum reaching a diameter of 4 cm., while those about the abdominal aorta decreased in size to the region of the bifurcation, where they measured about 2 cm. in diameter, but were of the same appearance as those described above.

In situ structures about the innominate veins were dissected, primary incision being extended at right angles laterally along the left clavicle. No abnormality or rupture of the thoracic duct could be found. In posterior mediastinum duct, esophagus and vessels were surrounded by the tumor, but none of these structures was invaded macroscopically. The heart, lungs, trachea, esophagus, aorta, thoracic duct, pancreas, kidneys and suprarenals were removed en masse. The duct was slit open and followed to its beginning branches. Its mucosa was smooth everywhere.

Microscopic Examination.—Sections from the retroperitoneal mass just below the diaphragm and from the cervical, axillary, clavicular, mediastinal, gastrohepatic, abdomino-aortic and iliac glands presented practically the same appearance. The normal markings were largely hidden by a diffuse accumulation of cells of the lymphocyte series, many of embryonic, undifferentiated type. They were mostly round, and varied considerably in size. The smaller cells were typical lymphocytes. The larger ones had less regularly outlined cytoplasm and nuclei. The cytoplasm was nongranular. The nuclei were paler, relatively larger and less distinct, and contained coarse chromatin granules. Many of the larger cells were multinucleated. Monasters and diasters were numerous, and an occasional multiple mitosis was seen. In a few places a moderate number of eosinophils were noted. In most of the lymph nodes, tumor cells were infiltrating the capsule and the surrounding fatty and fibrous tissue. Microscopic diagnosis, lymphoblastoma, malignant lymphosarcoma, round cell sarcoma.

Lung. At one side was an area of invasion by cells similar to those previously described as forming the tumor. These could be seen in the lymphatics along some vessels, but were also made out within the vessels. At the edge of this area these cells were advancing along the alveolar walls and into the alveolar spaces. Microscopic diagnosis lymphoblastoma.

Spleen. One section showed loss of normal splenic structure, a few trabeculae and arterioles lying in the midst of a diffuse growth of lymphoblastic cells similar to those described in the tumor. The stroma in places had undergone fibrinoid change. Another section presented fairly well circumscribed islands of tumor cells, between which splenic tissue was compressed with a relatively increased number of trabeculae. In such interinsular splenic tissue some sinusoids were greatly dilated, and there were clusters of endothelial leukocytes filled with hemosiderin. In the islands of the tumor cells were spots of apparent hemorrhage. In others small areas of fibrinoid change of stoma were seen. Occasional eosinophils were noted. Outlying from the larger islands of the tumor cells were smaller aggregations of similar cells suggesting lymph nodules. Some of these, however, involved cross sections of two or three trabeculae and one or two arterioles. Microscopic diagnosis, lymphoblastoma.

Pancreas. Four sections showed diffuse infiltration of the fat about the pancreas by lymphoblastic cells like those previously described, and more or less diffuse infiltration of the pancreas itself by like cells. The cells seemed to be advancing from without by expansion. In places small islands of glandular tissue were surrounded by such cells. In other places such cells were infiltrating only in the connective tissue stroma between the glands. Occasionally a group of pancreatic cells showed karyolysis or karyorrhexis or complete granular degeneration. Such groups were invaded chiefly by polymorphonuclear leukocytes. In some places there was a relative increase of fibrous tissue in the stroma, in which regions some acini were dilated with secretion and contained a few polymorphonuclear leukocytes. Among the invading lymphoblastic cells eosinophils were not infrequent Microscopic diagnosis, lymphoblastoma invading pancreas, causing injury, reaction and beginning sclerosis

---

[4] Dock Am. Jour. Med. Sc., 1907.

Final Diagnosis—Lymphoblastoma of cervical, axillary, clavicular, mediastinal, gastrohepatic, abdomino-aortic and iliac lymph nodes, invading pancreas and lung, compressing other structures adjacent to them and metastasizing in the spleen Chylothorax, bilateral Chylous ascites Gastric ulcers Hemorrhage into intestine Chronic endocarditis Chronic aortitis Edema of legs Fibrous pleural adhesions, bilateral Superficial ecchymoses Acute dermatitis of left leg Multiple leiomyomas of the uterus Senile ovaries Postmortem change in the suprarenals Chronic gingivitis Atalectasis of lungs

AN UNUSUAL CASE OF CHRONIC INTERSTITIAL NEPHRITIS

WITH FINDINGS IN BLOOD AND URINE*

ROBERT H HALSEY, M D
NEW YORK

History—A man, E O M, aged 39, married nine years, with no children, fruit grower, an occupation which he had followed for ten years, whose father and mother were living and well, as were four brothers and four sisters, he being among the younger of the children, had measles when he was a child, but after that time had had nothing more serious than "colds" in the head, and had not found it necessary to consult a doctor until March, 1915 His habits had been good, he rarely took a glass of beer, used three cigars a day, never more, and drank coffee or tea at meals three times a day He denied having had any venereal infection, and the Wassermann reaction was negative His appetite had always been good, his bowels regular, and his weight practically stationary, 180 to 185 he being about 6 feet tall

He believed his present trouble had begun in March, 1915, when he noticed his vision was becoming dim, for which he thought it necessary to consult an oculist at Poughkeepsie His oculist directed him to give up the use of tobacco, which advice he followed, though he was smoking only three cigars a day Soon after this he had periods of severe, persistent headaches with complete remissions The headaches were accompanied by loss of appetite increasing weakness and loss of weight, until June, 1915 when he was examined by his family physician, who diagnosed Bright s disease and prescribed a diet free from meat and salt, and 2 grains of sodium nitrite three times a day He had continued both the diet and medicine until he came under my observation During the summer and autumn he had continued his daily outdoor work, but had yielded to the advice of his physician to spend the winter in Florida, whither he was bound when he came to me on Nov 30, 1915

He walked into the office and desired me to express an opinion as to whether it was necessary for him to continue his journey south This is mentioned only to show that his symptoms were so slight as not to impress him or his family with the belief that he was seriously ill

On being questioned he said he was weaker than usual, and exertion made him a little breathless, at times his head ached and he had a little vertigo after he stooped over He could not see printed matter clearly to read He had little appetite, but his bowels moved regularly He had lost gradually some 15 or 20 pounds of weight in the course of the six months He said that during the previous week or ten days whenever he was about to lose consciousness in sleep, something seemed to give way and he awoke with a start This was particularly annoying at night, but during the day he might obtain, at intervals a few minutes sleep

Examination—The man was found to measure 6 feet tall and to weigh 165 pounds He was evidently undernourished, and the skin and mucous membranes were very pale The odor of the breath was distinctly urinous the tongue was flabby and pale, with a moderate coating over the posterior half, the tonsils were not abnormal, and though several of his teeth had been filled, there was neither pyorrhea nor decayed roots There was a very marked tremor of the muscles of the arms and legs Examination of the eyes showed normal reflexes, but the eyegrounds, as subsequently corroborated by Dr A E Davis, had several white areas, and three or four feathery hemorrhages The temperature was 97, the respirations 16 per minute, there was a good Litten diaphragm phenomenon, and the signs of a moderate emphysema The arteries were distinctly thickened and tortuous The rhythmic apex beat of the heart was seen and felt in the fifth interspace within the midclavicular line The orthodiagram of the heart measured 8 9 cm from midsternal line to apex, and 4 3 cm from midline to right border The aortic shadow was 4 5 cm wide There were no thrills felt, and the first sound at the apex was loud and clear, with reduplicated second sound At the junction of the third rib with the left edge of the sternum there was a distinct systolic blow, with a loud, ringing second sound The measure of the blood pressure showed it to be systolic 270 mm, diastolic 140 mm mercury, and there was a pulse frequency of 80 The electrocardiogram indicated a preponderance of the left ventricle The abdominal examination was negative There were no glandular enlargements The deep reflexes were greatly exaggerated, and a fine tremor of the muscles could be felt when the extremities were held There was neither Kernig nor Babinski phenomenon, and there was no edema of the ankles

TABLE 1—SHOWING AMOUNT OF BLOOD SUGAR, URIC ACID UREA NITROGEN AND CREATININ THE CARBON DIOXID COMBINING POWER OF BLOOD PLASMA, AND THE RATIO OF UREA OF BLOOD AND URINE AS WELL AS PHENOLSULPHONEPHTHALEIN EXCRETION

Day in December 1915	Sugar	Uric Acid Mg per 100 c c	Urea Nitrogen Mg per 100 c c	Creatinin Mg per 100 c c	Carbon Dioxid		Ambard Ratio	Phenolsulphonephthalein
					C c.	Mg		
1	0 18	6 5	97	17 5	0.36	0 50		0
4	0.225	6.4	129	21.5	0 33	0 44		0
7	0 18	6.3	129	21.8	0.35	0 48	1.56	0
10	0 22	7 0	132	22 3	0.38	0 53		0
14	0.21	6 1	144	28.9	0.36	0 50		
17	0 20	5 6	150	24 2	0 27	0.33		
21	0 18	5 0	188	28 6	0.30	0.38		
24	0.24	7 7	200	26 7	0.24	0.27		

The blood examination revealed a secondary anemia with hemoglobin 35 per cent, erythrocytes 2,800,000, and a normal white cell and differential count. The urine excreted in twenty-four hours was 2,200 c c., with specific gravity 1 010, *no albumin and no casts The percentage of chlorid and* nitrogen was not determined No phenolsulphonephthalein[1] was demonstrated in the urine The chemical examination of the blood revealed a retention of the nitrogen[2] constituents as shown in Table 1 The urea nitrogen was 97 uric acid 6 6, creatinin 17.5, blood sugar 0 18, blood plasma carbon dioxid combining power 0.36 c c., or 0 50 mg

Treatment and Course—Because of these findings, he was continued on a carbohydrate diet[4] of cane sugar 250 gm and water 1 liter, and three days later a second examination of the blood was made This showed an increasing retention of urea to 129, and creatinin 21 5, in spite of the absence of nitrogen intake The carbon dioxid combining power of the blood plasma had diminished to 0 33 c c., or 0 44 mg There was no excretion of phenolsulphonephthalein on repeated tests

Satisfied that his condition was desperate,[5] because of the marked retention of nitrogen in the blood, I considered a functional test of the kidneys, such as suggested by Mosenthal,[6] to be contraindicated, and was contented to have examined the two-hour specimen for volume, specific gravity, percentage of sodium chlorid and nitrogen, and the presence of albumin or casts (Tables 2 and 3) This examination showed an increased amount for the night urine, but this should not be emphasized, since he was permitted fluid whenever he wished and, as his nights were restless, he drank considerable The inability of the kidneys to concentrate was shown by the specific gravity of the specimens, which was low, varied only slightly, and diminished as death approached The low percentage of chlorids might be due to the salt-poor diet to which he was restricted, as well as to the fact that he had been so restricted for five months The nitrogen percentage remained low, even after increased intake

TABLE 2—SHOWING AMOUNT OF URINE VOIDED IN TWO HOUR PERIODS AND THE LOW, SLIGHTLY VARYING SPECIFIC GRAVITY, AND PERCENTAGE OF SODIUM CHLORID AND NITROGEN (DEC 9, 1915)

Time	Urine, C c	Specific Gravity	Sodium Chlorid		Nitrogen	
			Per Cent	Grams	Per Cent	Grams
8 to 10	500	1 010	0 30	0 150	0 44	0 220
10 to 12	130	1 008	0 40	0 520	0 39	0 507
12 to 2	160	1 008	0 30	0 480	0 41	0 656
2 to 6	350	1 010	0 35	1 225	0 42	1 470
6 to 8	165	1 010	0 35	0 577	0 43	0 709

After three days more of nitrogen-poor[7] diet, the blood examination showed the urea nitrogen to be 129 mg, uric acid 6 3, creatinin 21 8, blood sugar 0 18, carbon dioxid combining power of the blood plasma 0 35 c c, or 0 48 mg The restriction of his nitrogen intake was continued, and on December 10 examination of the blood showed the figure for urea nitrogen to be 132 mg, uric acid 7, creatinin 22 3, blood sugar 0.22, carbon dioxid combining power 0 38 c c, or 0 53 mg It is quite noteworthy that following the restriction of diet there was a slight rise in the carbon dioxid combining power, though an increased retention in the blood of urea and creatinin Because the urea nitrogen had increased, the nitrogen-poor diet was continued, and on December 14 the blood examination showed urea nitrogen 144, uric acid 6 1, creatinin 28 9, blood sugar 0 208, carbon dioxid combining power of the blood plasma 0 36 c c, or 0 50 mg

It was now quite evident the patient's condition was becoming more serious, for the nitrogen was increasing and the carbon dioxid blood plasma combining power was diminishing He had been on a protein-poor diet for fourteen days, and though the retention of nitrogen had continued to increase, it seemed unwise not to allow a small amount of protein to spare the body tissues, therefore he was permitted a diet containing some protein, though the nitrogen intake was still kept low, 30 gm of protein with nitrogen content of 4 8 gm and 1,800 calories On December 17 the blood examination showed urea nitrogen 150, uric acid 5 6, creatinin 24 2, blood sugar 0.20, carbon dioxid combining power of blood plasma 0 27 c c, or 0 33 mg The restricted nitrogen intake was continued and on December 21 the blood examination showed urea nitrogen 186 mg, uric acid 5, creatinin 28 6, sugar 0 184, carbon dioxid combining power 0 30 c c, or 0 38 mg During the night of December 21 he had a profuse epistaxis and began to complain of precordial pain On palpation over the second, third and fourth left interspace in the parasternal line, one could feel a friction rub, and on auscultation a to-and-fro friction sound could be heard The venous pressure at this time had evidently increased, as shown by the marked engorgement of all the veins of the extremities The pulse rate increased somewhat over 100, and the temperature rose from 96 4, which it registered on December 20, to 98 6 On December 24 the blood examination showed urea nitrogen 200, uric acid 7 7, creatinin 26 7, blood sugar 0 236, carbon dioxid blood plasma combining power 0 24 c c, or 0 27 mg

This examination showed the most critical condition, and death followed, December 25, at 10 40 a m, without coma or convulsions, but with a very rapid failure of the heart, which was evident for about an hour and a half before death

The pulse rate remained about 80 until December 23, when it began to increase and rose to 100, coincident with the development of his pericarditis The rate of 100 to 110 was maintained until just before death, when it reached 120, and later became imperceptible at the wrist The temperature remained about 98 until December 20, when it gradually sank to the point of 96 6, and on December 21 reached 96 4 Then with the onset of his pericarditis it gradually rose to 98 6, which it reached at the time of his death Respirations were usually 18 to 20, except during the periods of sleep, when they rose to from 30 to 36, and were accompanied by vigorous twitching of the legs and arms, but at no time was there a Cheyne-Stokes phenomenon

The intake of fluid varied between 1,000 and 2,500 c c, and the output reached as high as 2,100 c c, the amount usually being between 1,100 and 1,700 c c, until the day before death, when it sank to 500 c c, and this was obtained by catheterization, as he was unable to void during the last forty-eight hours Twice during the period of observation he vomited, and there were several watery bowel movements in the day Aside from the increasing uremia, this was unaccounted for

The blood pressure when he first came under observation was, systolic 270, diastolic 140 mm of mercury, with a pulse frequency of 80, gradually diminishing to systolic 215, diastolic 110, about December 10 Then the diastolic pressure rose to 130, systolic remaining at 220, until December 16, or nine days before death, when the systolic fell to 190 and the diastolic to 110 mm of mercury, remaining so for two days On December 18 the systolic pressure rose to 225 and the diastolic to 130 mm of mercury, again gradually diminishing until December 24, when the systolic registered 175 and the diastolic 90 With the onset of the pericarditis there was a marked rise in the venous pressure

Shortly after entering the hospital he began to have attacks of epistaxis, which were easily controlled by ice water applied to the face, until December 21, when he had a profuse hemorrhage Subsequent to this the pericarditis became evident and the next day, December 23, he complained of a pain in his chest, and the same day the palate and uvula became edematous

TABLE 3—SHOWING AMOUNT OF URINE VOIDED IN TWO HOUR PERIODS AND THE LOW, SLIGHTLY VARYING SPECIFIC GRAVITY, AND PERCENTAGE OF SODIUM CHLORID AND NITROGEN (DEC 13, 1915)

Time	Urine C c	Specific Gravity	Sodium Chlorid		Nitrogen	
			Per Cent	Grams	Per Cent	Grams
8 to 10	115	1 008	0 35	0 402	0 40	0 400
10 to 12	150	1 000	0 35	0 525	0 39	0 585
12 to 2	190	1 008	0 35	0 665		
2 to 4	50	1 005	0.30	0 150	0 30	0 150
4 to 6	170	1 003	0.35	0 595	0 30	0 612
6 to 8	180	1 008	0.30	0 540	0 35	0 630

The first chemical examination of the blood (Table 1) shows urea nitrogen, uric acid, creatinin and sugar to be well above normal, and the combining power of the blood plasma to be at the low figure of 0 5 As subsequent examinations were made, each one of these figures showed a progressive impairment of his metabolism, as indicated by the increasing retention of nitrogen and decreasing combining power of the blood plasma Of four tests of the phenolsulphonephthalein, after only one was a trace of the dye found in the urine, the others being absolutely negative The ratio between the urea in the blood and the urea in the urine, as suggested by Ambard, gave a figure of 1 58, while with McLean's index[8] the figure of 0.27 was obtained, both showing very strikingly the impaired secretory power of the kidney

It is particularly interesting to note that during the time he was on the nitrogen-poor diet the creatinin jumped from 17.5 to 21 5 and remained at that figure for six days, subsequent to which it made a further increase to 28 9, at which point it remained until the day before death The same temporary cessation of retention is shown in the urea figures, which for a week subsequent to the nitrogen-free diet remained almost stationary, but subsequently increased very rapidly, reaching the high point of 200 the day before death

SUMMARY

A case of chronic nephritis with hypertension is described in which the following history was traced

1 The respiration rate was of an unusual periodic type, increasing during sleep to almost double the frequency of the waking period, but not of the Cheyne-Stokes or Biot type, though uremia was the cause of death

2 The blood sugar and the blood nitrogen, as well as the carbon dioxid combining power of the blood plasma, are shown as indicating the condition and course of the disease

3 The absence of phenolsulphonephthalein excretion, together with other urinary findings, are recorded

4 Though the arteriosclerosis, retinal changes and high pressure were extreme, there was the physical evidence of only the slightest hypertrophy of the heart

5 Two days before death a profuse epistaxis occurred, followed by edema of uvula and palate and the development of fibrinous pericarditis

CONCLUSIONS

1 With the examination of the urine only, the seriousness of this patient's condition would not have been discovered

2 The phenolsulphonephthalein excretion test is of value to indicate the status praesens of the patient, but the amount of urea and creatinin in the blood, particularly the latter, give a definite clue to the progress and prognosis

158 West Fifty-Eighth Street.

Preservative Value of Cleanliness.—Modern bacteriology has placed on cleanliness a preservative value which may appear surprising in respect to its efficiency, particularly in conjunction with low temperatures which inhibit the development of micro-organisms detrimental to foods As an example of what such sanitary precautions can accomplish in the case of readily deteriorating milk Sherman states that 'three American dairy farms exhibited raw milk at the Paris Exposition of 1900, one of them sending weekly shipments throughout the summer, each of which was kept on exhibition in the raw state without spoilage until the next shipment arrived It was difficult to convince the jury of European experts of the fact that 'cleanliness and cold' were the only preservatives needed to accomplish the keeping of raw milk in a fresh sweet condition for two to four weeks in midsummer' Precisely such methods combined with modern transport facilities have made it possible to extend the range of milk supply in our large cities literally hundreds of miles and to bring an indispensable food at a reasonable price into every home. There is, indeed, a profound difference between marketing milk in the familiar manner now practiced and the older mode of distribution when goats or cows were driven in front of the home to be milked there.—Changes in the Food Supply and Their Relation to Nutrition, Lafayette B Mendel

THE EXAMINATION OF NORMAL GASTRIC SECRETION BY THE FRACTIONAL METHOD

EUGENE S TALBOT, JR., M D
CHICAGO

In view of the peculiar advantages which might be gained from a study of the entire cycle of secretion during gastric digestion, a considerable number of both normal and pathologic stomachs have been analyzed at the Wesley Hospital during the last eighteen months, according to the method of Rehfuss As the result of this work, it is believed that the method of fractional gastric analysis offers the only logical method of examination for determining the true secretory and motor state of normal and abnormal stomachs, and that consequently it should replace the older stomach tube method, by which merely the momentary secretory and motor condition can be estimated

In all, about 150 cases have been examined by the fractional method These include a normal series on proved healthy medical students and nurses, and an abnormal series on private and clinical hospital patients The clinical diagnosis in the pathologic series, based on the symptoms, physical examination, laboratory and Roentgen findings, was checked in a large number of cases by a pathologic diagnosis at operation

The technic employed was that of Rehfuss with a number of changes and additions In all cases the tube was first inserted into the twelve hour fasting stomach, the entire content being removed, measured and examined for free hydrochloric, lactic and total acidity, and for mucus, bile and food particles A straight Ewald meal consisting of two slices of bread and two glasses of water was immediately introduced into the empty stomach and the tube reinserted At fifteen minute intervals, 5 c c specimens were withdrawn until the specimens were macroscopically free from food particles and until the free and total hydrochloric acid had returned to approximately their relative positions as found in the fasting content Care was exercised against the swallowing of mucus throughout the examination, and the individual was protected as far as it was possible from all forms of psychic stimulation, especially that of the sight or smell of food Titration was performed with tenth normal sodium hydroxid Phenolphthalein was used as indicator for total acid, and dimethyl-amidoazobenzol for the free acid

In this way a curve was constructed, beginning with the fasting content, and on fifteen minute analyses after the administration of the Ewald meal until the aspirations showed no further food remnants or until the secretion had returned to that of the fasting state

Only by this method of introducing the test meal into the empty stomach can the true appetite secretion, or with this lacking, the secretory response to food stimulation, be ascertained

In the normal series, consisting of twenty-four cases, care was taken to select only those subjects who were free from both general and gastro-intestinal abnormalities so far as history and physical findings disclosed In six of the series a second analysis was run under as nearly the same conditions as the first as possible, in order to determine whether repeated examinations of the contents of the same stomachs would give the same secretory curve At least two weeks elapsed between the first and the second analysis in all cases

Table 1 gives the results of analysis of the residuum in the series of twenty-four fasting stomachs Summarized, the highest total acidity was 40 in terms of tenth normal sodium hydroxid, the lowest was 5, with an average of 17 The highest free hydrochloric acidity was 30, while in 62 5 per cent the residuum contained no acid, giving an average of 6⅜ free acid for the series The greatest quantity was 210 c c, the smallest 5 c c, with an average of 48⅙ c c Bile was present in the residuum in 41 66 per cent of cases

The surprising feature in this as in the Rehfuss series is the quantity of residuum which may be found in the normal fasting stomach by this method as compared with former ideas of the boundaries of normal, ranging for 20 to 60 c c, according to various authorities "The old tube which is propelled from above has its position always fixed", consequently, if either too little or too much tubing is introduced, the eye of the tube, being above the most dependent portion of the greater curvature, is unable to take up the entire amount of residuum The eye of the Rehfuss tube, on the other hand, seeks the most dependent portion of the greater curvature by gravity, and remains in this position for a considerable time, as I have repeatedly proved by passing the tube before the fluoroscope and allowing a stream of bismuth suspension slowly to pass through the tube and settle along the floor of the stomach Since the olive of the Rehfuss tube seeks the most dependent portion, it would seem quite an unnecessary procedure to aspirate with the patient standing or lying in the various postures, recommended by Rehfuss, unless an actual deformity were present in the contour of the stomach

TABLE 1—RESIDUUM IN TWENTY FOUR NORMAL FASTING STOMACHS

In Table 2 are recorded the essential features of the curves of secretion in the normal series

A detailed study of the various normal charts, in the vast majority of cases, will show a considerable drop in both the total and free acid values at the first fifteen minute period as compared with the fasting residuum This abrupt fall is undoubtedly due to the dilution of the appetite secretion by the Ewald meal In seventeen of the cases, either the total or the free or both waves began to ascend within the first fifteen minutes, in four cases the rise began during the thirty minute period, in two cases in forty-five minutes and, in one, only at the end of one hour Consequently it will be seen that in six instances in the series, there was either no appetite secretion evoked by the Ewald meal or that the reaction to the psychic stimulation was too slight to overcome the diluting action of the meal, and that the beginning of the wave occurred only as the result of the food stimulation

The curves resulting from the absence or diminution of the appetite secretion closely resemble the delay of the secretory waves observed in the pathologic series in three chronic alcoholic gastritis cases with associated portal congestion

The varying effect which the Ewald meal may produce on the appetite secretion in different individuals, and its consequent effect on the character of the secretory curve, should not be overlooked

In not a single instance in the normal series did we record the early steep rise of either free or total acid, classified by Rehfuss as the hypersecretory type of normal curve This form of curve, however, is frequently seen in pathologic cases, and the steep ascent is called an "irritable rise," since these cases almost without exception have shown a high free hydrochloric acid secretion in the fasting stomach

In summarizing the time of occurrence of the high point in secretion in the series, it will be seen that in the case of the free acid, this occurred in twenty of the twenty-four cases between the one hour and fifteen minute and one hour and forty-five minute periods, with the greatest number occurring at one hour and a half, and that in not a single instance did it occur at the one hour period, the conventional time for removing the Ewald meal, with the old tube On the other hand, in two instances the high point was attained in forty-five minutes In general, the same holds true in the case of the high point of the total acid curve, this occurring in nineteen of the twenty-four cases between one hour and fifteen and one hour and forty-five minutes, with the greatest number at the one hour and fifteen minute period, and with but three instances in which the high point was at one hour That the high point of both curves tends to occur at a later point than the one hour period is even more strikingly demonstrated in the pathologic series, in cases showing some form of continued gastric irritability It is improbable that any abnormal delay in the occurrence of the high point of secretion was caused by the introduction of the test meal into the empty rather than the fasting stomach, since in fifteen of the twenty-four cases the fasting stomach showed no free hydrochloric acid which might have hastened the secretion, and since in the vast majority of cases the secretory response occurred at the normal time

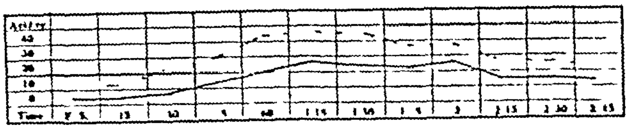

Chart 1 —Composite curve made by plotting the average acidity of the twenty four normal stomachs at each fifteen minute period broken line total acidity solid line free acidity F S fasting stomach

The high point of secretion varied from forty-five minutes to two hours and fifteen minutes after the test meal was taken Since it is not at all unusual to see a difference of 30 or even 50 in acid concentration in a single fifteen minute period, the fallacy of attempting to determine the true secretory state of a stomach by the analysis of a single specimen taken at a fixed time is evident In the pathologic series there are many curves, showing a normal or hypoacidity at one hour, which at one hour and fifteen minutes or one hour and a half show a marked hyperacidity, consequently it would seem that a hypothesis is erroneous which assumes on the basis of a single one hour analysis that a hyperacidity history with a hypoacidity finding is pathognomonic of an ulcer, since at one hour and a half there may be enough free acid present to cause this picture, especially if the acid is acting on a hypersensitive mucosa

In eighteen cases of the normal series, the free acid ranged between 20 and 60 with an average of 35½ In one instance the free acid attained a height of 100 without producing symptoms The height of the total acid curves ranged between 36 and 114, with the greatest number falling between 50 and 80

An examination of the general character of the secretory curves shows that there is no one form of curve which is common to all normal stomachs, although in general the vast majority of the normal series bore certain similar characteristics The pause before the evident secretory response, usually occupying the first fifteen to thirty minutes, was followed in most instances by a gradually ascending limb, the total acid curve usually rising first and diverging from the free wave The summit of the ascending limb most frequently occurred in from seventy-five to ninety minutes In one half of the series, the summit of the curve was sustained for from thirty minutes to two and one-half and even three hours, while in the other 50 per cent of cases, a more or less acute summit was followed by relatively short descending limbs which tended to converge Although we believe that Pawlow, Carlson and others have practically established the fact that normally "the gastric acid, as it flows from the glands, possesses a constant acidity," we do not believe that Rehfuss has substantiated this fact in his experiments The determining factor as to whether the summit of a curve is sustained or abrupt is entirely dependent on the duration of the balance between the intensity and duration of acid secretion, food fixation and the emptying power of the stomach, and consequently a plateau curve is evidence only of a sustained equilibrium, and is no proof of a secretion of a uniform concentration

In a number of cases, a temporary secondary rise of the curve took place after the stomach was empty of food, and apparently after the digestive cycle had been completed This secondary rise usually occurred within the first thirty minutes after the return of the acidity of the secretion to that of the fasting stomach, but it has been noticed as late as one and one-half hours after the apparent completion of the digestive cycle We attribute this secondary rise, which has been seen so frequently in the normal series, to a fluctuation in the rate of the continued secretion, during the period of cessation following the gastric cycle, rather than to mechanical irritation incident to the presence of the tube

The motor power as demonstrated by the disappearance of all food particles from the fifteen minute samples was very uniform in the normal series In twenty of the twenty-four cases, the stomach was empty in from one hour and forty-five minutes to two hours and a half The emptying time was evidently unaffected by the duration of the pause before the secretory response, and by high concentration of the hydrochloric acid secretion In one case in which the secretory response was delayed for one hour, the stomach was empty in two hours, while in another case in which the response occurred during the first fifteen minutes, the stomach was not empty for three hours In the case in which the free acid attained a height of 100 the stomach was empty of food in two hours and fifteen minutes, showing that a high acid concentration per se in this case at least produced no delay in the emptying time In only a very few instances did the presence of the tube cause gagging, and in these cases only during the first five or ten minutes, so that motility was probably not reduced by nausea

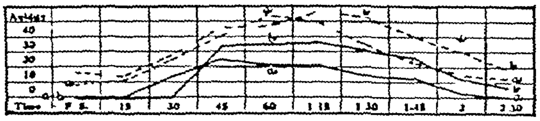

Chart 2 —Two curves from the same stomach with sixteen days intervening broken line total acidity solid line free acidity arrow empty of food F S, fasting stomach

The results of second examinations of the content of the same stomachs showed that although a normal individual will not always give exactly the same curve, the general main characteristics of the curve are identical The fasting residuum in both analyses gave total and free acidity of almost the same concentrations The high points of the waves occurred in practically every instance at the same time, were approximately of the same height and were generally of the same character, whether acute, rounded or plateau The greatest difference in emptying time in the two analyses was forty-five minutes, and this occurred in but one case The main difference in the contour of the curves was apparently caused by a variable response to the appetite stimulation

CONCLUSIONS

As the result of this work, we believe that the fractional method of gastric analysis should replace the old tube method

The true secretory curve of digestion can be determined only if the test meal is introduced into the empty stomach

A much larger quantity of residuum may be obtained from the symptom-free fasting stomach by the Rehfuss tube than was formerly considered to be within the limits of normal

The intensity of appetite secretion is variably influenced by the Ewald meal in different normal individuals

The difference in the time of occurrence of the high point of secretion and the rapidity of the change in acid concentration make it impossible to determine the true secretory state of a stomach other than by the fractional method of analysis

A plateau type of secretory curve is no proof of the secretion of an acid of uniform concentration

There is no one form of secretory curve common to all normal stomachs, although the vast majority of normal curves have certain characteristics in common

The contour of a given normal curve is dependent on the following main factors—the intensity and duration of appetite secretion as influenced by the test meal, the amount of gastric mucus, the concentration of food secretion, and the emptying time of the stomach

The emptying time of the normal stomach is fairly uniform

Many phenomena associated with the normal gastric cycle of digestion as determined by the fractional method of analysis have yet to be explained

122 South Michigan Avenue

Psychology of the Witness—The reports of the witness are always combinations of objective and subjective factors Emotions, decisions, thoughts, may influence his account of the past experience, and, even where the interest is entirely devoted to the external stimuli, the subjective apprehension and attention must play a role It is possible that the original sensory perception was defective, or, secondly, that the apprehension at the time of the perception was erroneous Thirdly, the disposition for the memory images may have changed in the course of time so that a correct reproduction has become impossible Fourthly, the will to reproduce the memory ideas may not have been intense enough to overcome suggestions or autosuggestions or to secure completeness Finally, the witness may have lacked the ability to express his ideas correctly Only if the process were free from disturbances at all these points can the testimony count as an objective report Each of these sources of mistakes can be examined by the psychologist It is clear, however, that three different types of psychological facts must be considered —Psychology General and Applied, Munsterberg

LAMINECTOMY WITH SIMPLE EXPOSURE OF THE SPINAL CORD

ITS EFFECT ON THE REFLEXES AND ON THE SYMPTOMS OF SPINAL DISEASE *

CHARLES A ELSBERG, M D
Surgeon to the New York Neurological Institute
AND
PEARCE BAILEY, M D
Physician to the New York Neurological Institute
NEW YORK

We feel that the time has come for a distinction to be made between those laminectomies in which the operation relieves pressure exerted on the spinal cord, by tumors, by collections of fluid or in other ways, and those in which there are no evidences visible at the operation of any compression of the spinal cord Hitherto, all such operations have been grouped under the general term of spinal decompression

In 1912, we published a report of seven cases of spinal disease, in which great improvement followed the removal of the spinous processes and laminae, with incisions of the dura Since that publication, we have had eight additional cases, and the course in all of them was profoundly influenced by the operative interference The title of that paper was "Spinal Decompression," but in only two of the cases was any actual increase of intradural pressure found, in these two, we naturally inferred that the improvement which followed the primary operation was due to the relief of intradural pressure after the free removal of spinous processes and laminae, with incision of the dura The improvement in the others, however, and in eight cases which we have had since, could be attributed to no such cause, for there was no compression of the cord

The present paper concerns itself exclusively with the cases in which there is no compression and in which the exposure itself is the only agency which can account for the change in the symptoms which so frequently follows the operation In this paper, therefore, in which we make use for the first time of the title of "Laminectomy with Exposure of the Spinal Cord," we shall limit ourselves to the considerations of the effects of spinal exposure in such cases of spinal disease in which there is no demonstrable increase of intradural pressure

The postoperative results have been so striking that the conclusion is unavoidable that surgical exposure of the spinal cord, even in the absence of increased intradural pressure, may of itself effect some change on the spinal cord which benefits or checks the symptoms of certain forms of spinal cord disease, and we feel that the procedure merits a name to distinguish it from laminectomies which relieve pressure

It is not always possible to determine before the exposure is actually made whether or not there is pressure to be relieved Consequently, the term "laminectomy with exposure" can be used with certainty only after the operation is completed We have no final physiologic explanation of the phenomena which follow such operations, although we shall suggest certain possibilities

---

* Read at the meeting of the American Neurological Association, Washington, D C, May 9, 1916

THE IMMEDIATE EFFECT OF LAMINECTOMY AND INCISION OF THE DURA ON THE REFLEXES

As has already been pointed out by one of us,[1] laminectomy and incision of the dura often have an immediate effect on the spinal reflexes. In many cases the knee and ankle jerks become markedly depressed or disappear altogether within thirty minutes of the opening of the dura, and this depression or disappearance of the reflexes may persist for from six to twenty-four hours. These changes often affect all the spinal reflexes, whatever part of the spinal cord may have been exposed by the operation. We have seen the reflexes of both upper and lower extremities modified after an operative interference in the middorsal region, but more often the reflexes below the level of the operative exposure are affected.

These phenomena might be explained by trauma to the cord during the operation or by bleeding into the membranes. But often the diminution or loss of the reflexes occurs when the operation has been very simple without appreciable injury to the cord itself or bleeding into its membranes. Since a similar change in the reflexes may occasionally be observed after simple spinal puncture, it is fair to conclude that changes in intradural pressure conditions with resultant modification of the spinal circulation are the important etiologic factors. We have not observed these changes after operations in which the dural sac remained unopened, but a similar disappearance of the reflexes is often observed after severe trauma to the skull or spinal column.

It is more remarkable that pathologic changes in the reflexes, such as exaggeration of the knee jerks, ankle clonus and the Babinski phenomenon, which had existed, disappear and only the normal reflexes are obtainable for a number of hours or days after an operation on the spine which has consisted of a laminectomy and incision of the dura and at which *no* definite spinal lesion could be discovered. We have observed these changes in a large number of patients. One of us has performed an exploratory laminectomy in the upper dorsal region on a young woman who had symptoms of disseminated sclerosis with a distinct sensory level. The patient presented, among other physical signs, an inversion of the triceps reflexes, that is, percussion of the triceps muscle was followed by marked flexion at the elbow. After the operation, which failed to show any macroscopic abnormality, the normal triceps reaction (movement of extension at the elbow) returned.

In another patient, in whom the exploration failed to discover any lesion, ankle clonus, and the Babinski, Mendel and Oppenheim phenomena disappeared for thirty-six hours after the operation, during which period the reflexes were normal. We have twice, in cases of suspected multiple sclerosis, seen the abdominal reflexes return for twenty-four hours after an exploration. In one of the patients, horizontal nystagmus, which had existed before the operation, could not be obtained for more than one day after the surgical interference. Similar results have been obtained for motor power.

We recently operated on a man who had a spastic paraplegia of both upper and lower extremities with a marked stiffness of the neck, there were fleeting sensory disturbances affecting mainly the pain and temperature senses up to the level of the sixth cervical segment. In spite of the fact that the diagnosis of multiple sclerosis seemed most probable, an exploration was decided on. The surgical interference failed to demonstrate any macroscopic lesion of the cord, but a decided functional improvement occurred which lasted for almost two months before the former symptoms returned. After the operation, the movements of the neck were much more free. The fingers and the wrists, which before were held stiff and almost motionless, could be moved freely two weeks after the interference. The increase in the strength of both upper limbs was very distinct, and the strength of the hand grips became excellent. The patient was soon able to walk without a cane or other assistance, and whereas formerly he dragged his feet when he walked, he now lifted them quite normally. The spasticity had largely disappeared from the legs, although the knee jerks were still active, and clonus and the Babinski reflex existed. As stated above, the condition of the patient three months after the operation was as bad as before the laminectomy. We have seen this temporary improvement in several patients, and shall keep this patient under continual observation. In another one of our cases (Case 1 following), a second improvement began a few months later, and all of the symptoms of spinal cord disease disappeared within six months.

The exposure of the cord to atmospheric pressure and possibly to light must have a profound effect on the spinal circulation, and as a result, the irritability of the spinal tissue must be greatly modified. There can be no *direct* effect on the reflex centers (nerve cells) in the spinal cord because the changes in the reflexes occur both above and below the part of the cord exposed. For the same reason, the change cannot be due to a direct inhibition of the sensory parts of the reflex mechanisms. We are therefore forced to the *hypothesis of an increased inhibition from the brain* centers through the pyramidal tracts. This may be due to an increased irritability of the centrifugal fiber tracts. If the reflex stimuli which pass to the cord through the posterior spinal roots were activated and regulated by stimuli from higher centers, it is possible that a loss of such activation or stimulation might diminish the conductivity of the centripetal fibers in the posterior roots, which would then be followed by a diminution in the reflexes. All this is still in the realm of speculation, the problems form a promising field for experimental investigation.

EFFECTS OF LAMINECTOMY WITH INCISION OF THE DURA ON THE SYMPTOMS OF SPINAL DISEASE

In addition to the immediate and temporary modifications in the reflexes and motor power just described, there are other changes which are more permanent, and which we have observed after spinal operations in which nothing was found to explain the symptoms. Either the improvement has been immediate and marked, or an immediate improvement in motor and sensory disturbances was followed, in from one to two days, by a return to the conditions as they existed before the operation but with later gradual improvement, or a change for the better began a few weeks after the operation.

In several of the patients who were markedly improved, the indications for an operation were very indefinite and the operation was performed because we had had remarkable experiences in other patients In several of the patients, satisfactory evidence of a localized lesion was not obtained, and the operator was led to expose the part of the cord which seemed most affected by the disease Sometimes the operation was performed at the level of the greatest motor disturbance, at other times at the level of most marked sensory loss

---

[1] Elsberg, C. A.: Tr. New York Neurol. Soc., Jour. Nerv. and Ment. Dis., 1911, xxxviii, 695.

The improvement has generally been gradual, extending over many months or years Within three months of the operation, we have seen exaggerated knee and ankle jerks return to the normal, and ankle clonus and the Babinski reflex disappear, at the same time that the spastic lower limbs gradually relaxed In the case of a patient with flaccid paralysis of the lower half of the body and the extremities of three months' duration, improvement began a few weeks after the operation Within six weeks the knee and ankle jerks had reappeared Eight months later much power in the limbs had been regained, and the patient was able to walk around with the aid of a cane The improvement is still continuing

Reports of three cases, typical of the results we have seen, are given in detail

REPORTS OF CASES

Case 1—(Med No 606, Surg, 249)—*Multiple sclerosis? Exploratory laminectomy, negative findings, temporary marked improvement in symptoms, relapse followed by improvement, and finally complete recovery*[2]

History—F L T, a clerk, aged 26, admitted to the service of Dr Bailey at the New York Neurological Institute, Sept 19, 1910, was an athlete, and declared that he had been perfectly well until about three months before admission Then he began to be unsteady on his feet, and this was soon followed by a numbness in his lower limbs The symptoms gradually grew worse, and he found that his lower extremities became tired on the least exertion At times he would have a tingling and burning sensation in his lower limbs He felt that the limbs were becoming weak and stiff He was in the hospital for one month during which time he was found to have a spastic paraplegia of the lower extremities without any sensory disturbances Wassermann tests of the blood and cerebrospinal fluid were negative, and the fluid was normal in all respects He left the hospital in October, but returned, December 4, with all of the symptoms aggravated At this time both lower extremities were very spastic, with exaggerated knee and ankle jerks, clonus and Babinski reflex The abdominal reflexes were wanting There was now a diminution of sensation up to the level of the twelfth dorsal spine, but tactile sensation was hardly, if at all, affected After a short stay in the hospital, he again left, only to return, Jan 8, 1911 The burning sensations in the lower limbs were worse, and were accompanied by shooting pain in the left groin, and the lower limbs were weak and spastic, so that he could hardly drag himself around with help There was some slight sexual disturbance The right lower extremity was now weaker than the left, both knee jerks were exaggerated, the right one more than the left Ankle clonus and the Babinski reflex were elicited on both sides, more marked on the right The abdominal reflexes could not be obtained There was a distinct but not well marked diminution of all three sensations below the level of the tenth dorsal segment, but tactile sensation was only very slightly disturbed, while pain and temperature were definitely diminished The case had been considered one of multiple sclerosis and not one for operative treatment, but the patient urgently requested that no matter how poor the outlook, he be given a chance by operation This was finally acceded to, and Dr Elsberg performed a laminectomy, January 20

Operation—The spinous processes and laminae of the seventh, eighth, ninth and tenth dorsal vertebrae were removed Incision of the dura and exploration failed to reveal anything pathologic, excepting for the fact that the cord was of somewhat irregular consistency The cardiac and respiratory pulsations were normal, and there was no excess of cerebrospinal fluid All sides of the cord were carefully investigated, but nothing abnormal could be discovered There were no adhesions between the membranes, and these seemed normal The wound was closed in the usual manner

Postoperative History—Recovery from the operation was without incident excepting for the presence of a very distressing hiccup for a few days The wound healed by primary union

One week after the operation, the patient could recognize heat and cold on all parts of both lower limbs, and the hypesthesia and the hypalgesia were much less marked He was able to move his lower limbs much more freely, a great deal of the spasticity had disappeared Knee jerks were only slightly exaggerated, and there were no clonus, and no Babinski phenomenon Three weeks later he could move his lower limbs quite freely, but the spasticity was more marked When the patient was discharged from the hospital two months later, his condition was the same as before the operation The lower limbs were again spastic, and he had exaggerated knee jerks, double ankle clonus and Babinski reflex The abdominal reflexes were present and equal on both sides Sensation was, however, normal over the entire body excepting for a small area of hypesthesia over the anterior surface of the left thigh and a very slight diminution of pain and temperature sense over the left lower extremity The sensory disturbances were, however, so slight that their extent could not be determined The case was now considered one of multiple sclerosis

For about two months after leaving the hospital, the patient's condition was not much changed Then improvement began and steadily progressed Within four months he was practically well, all signs of spasticity had disappeared, and the reflexes in the lower extremities were normal on the right but still slightly exaggerated on the left side When last seen (April, 1916) he was perfectly well and about to be married

Case 2—*Syphilitic disease of the spinal cord with flaccid paraplegia Exploratory laminectomy Very great improvement*

History—E D, aged 50, single, a patient of Dr James Pedersen, was seen by us in 1914 The patient contracted syphilis in 1896 and was thoroughly treated for two years In November, 1898, he began to notice a numbness in both lower extremities and began to have difficulty in walking Intensive antispecific treatment was again begun, and the numbness and weakness in the lower extremities disappeared gradually during the course of three months

In 1911 he developed diplopia and also began to have some difficulty in walking The diplopia cleared up after antispecific treatment with salvarsan, mercury and the iodids, but some weakness in the lower extremities persisted In September, 1914, the left lower extremity became rapidly worse Two months later both lower limbs were paralyzed, and the patient had lost all control of the bladder and rectum In spite of most energetic antisyphilitic treatment, the condition became steadily worse The Wassermann reaction was negative in both blood and cerebrospinal fluid

Physical Examination—Nov 18, 1914, the general condition was good The cranial nerves and upper extremities were normal The abdominal reflexes could not be obtained The cremasteric reflexes were absent The left lower extremity was completely paralyzed, on the right side, the patient was able to move his toes slightly Neither knee jerks nor ankle jerks could be elicited There was no Babinski or other pathologic reflex There was a very slight disturbance of all three sensations up to the level of the sixth dorsal segment The sensory loss was nowhere very distinct, but was more so on the right side than on the left, and the pain and temperature were more affected than the tactile sensation Deep muscle sense was normal The diagnosis of a localized degenerative process on a syphilitic basis was made The patient was informed that the outlook was very poor, but that we had seen beneficial results from decompressive laminectomy in this type of case, and that we considered the operation indicated

---

[2] Reported in part in our previous paper

Operation—The patient was anxious to have everything tried, and after the matter had been explained to him, he asked to have a laminectomy performed This was done by Dr Elsberg, Nov 28, 1914 The spines and laminae of the fourth, fifth, sixth and seventh dorsal vertebrae were removed On incision of the dura a moderate amount of clear cerebrospinal fluid escaped The vessels on the posterior surface of the cord were distinctly enlarged There was no thickening of membranes or adhesion between them, no gross abnormality aside from a slight pinkish discoloration of the cord. The wound was closed in the usual manner

Postoperative History—Convalescence from the operation was uneventful The wound healed by primary union December 21 (four weeks after the operation), both knee jerks had returned, although they were elicited with difficulty and the right was more lively than the left The ankle jerks were present and weak and a Babinski reflex could be obtained on the right side There had been a considerable return of power in the lower limbs The patient could flex both lower limbs at the knee, but the left lower extremity was much weaker than the right Stroking of the abdominal wall elicited distinct abdominal reflexes Eight weeks after the operation the patient was so much improved that he could raise both limbs from the bed, but the left limb was much weaker than the right one

Four months after the operation, the patient was able to stand with assistance The left knee was still weak, and the patient was given an appropriate brace for support The power in the right lower extremity was almost normal The patient now had some control of the vesical and rectal functions The slight sensory disturbances which had existed before the operation had disappeared, and sensation was normal over all parts of the body

Ten months after the operation, the patient was able to walk around with assistance Extension at the left knee was still weak, so that the patient had to continue to wear a brace, but the power in the limb as a whole was much improved The vesical and rectal functions were normal The patient declared that he was improving slowly but constantly His only treatment consisted of massage, electricity and regular exercises

CASE 3—*Multiple sclerosis Exploratory laminectomy, great improvement*[3]

History—M M, aged 30 an Italian, was admitted to the New York Neurological Institute on the service of Dr Peterson, Dec 16 1914 Seven months before, the patient noticed that he was losing control of his bladder and that at times he was incontinent of urine This was soon followed by constipation and by loss of control of the anal sphincters after taking a laxative. About six months ago, his legs became weak and stiff The left limb was first affected, but the right leg soon became as bad as the left one The patient also noticed that he had a numb sensation on some parts of his lower extremities Walking became increasingly difficult on account of the stiffness of his lower limbs

Physical Examination—On admission, the patient presented all the signs of a spastic paraplegia, he was hardly able to drag himself along with the help of two canes Cranial nerves and upper extremities were normal The upper abdominal reflexes were present but weak, the lower abdominals and cremasterics could not be obtained The lower extremities were weak and spastic, the left more than the right The knee jerks were lively the left more so than the right, the ankle jerks were lively the left more than the right, double inexhaustible ankle clonus, and the Babinski and Mendel-Bechterew phenomena were present There was no loss of deep muscle sense in the lower limbs Tactile sensation was normal all over the body, there was a distinct diminution of the pain and temperature senses up to the level of the eighth dorsal segment The disturbance of sensation was most marked over the right lower extremity, and over some areas there was complete analgesia The sensory disturbance was most marked over the anterior surface of the body The Wassermann test and Roentgen-ray examination were negative

Operation—December 21, an exploratory laminectomy was performed by Dr Elsberg The spines and laminae of the fifth sixth seventh and eighth dorsal vertebrae were removed and the dura was incised There was free escape of cerebrospinal fluid No macroscopic change in the cord was observed, respiratory and cardiac pulsations were normal, the vessels were normal, there were no adhesions or other abnormality A probe was passed upward and downward in front of and behind the cord without meeting any obstruction The dura, muscles, fascia and skin were sutured in the usual manner

Postoperative History—Convalescence was uninterrupted, the wound healed by primary union

January 14, control of the bladder was much improved, the patient had good control in the daytime Sensation over the limbs was normal The upper abdominal reflexes were present, the lower right were present and weak, the left could not be obtained Power of extension and flexion of the lower limbs was now good The knee jerks were lively and equal double exhaustible ankle clonus was still present

March 11 the patient could lift both limbs from the bed equally well Walked around the ward without any evidence of spastic gait

From this time on the improvement was continuous The patient was presented at the meeting of the New York Neurological Society in February, 1916, as almost well His gait was normal, the power in the lower limbs was excellent, the reflexes were not exaggerated The abdominal reflexes were present and equal The patient stated, however, that he became tired very easily, and that at night he often had trouble with the bladder He was much satisfied with his walking

COMMENT

We shall not cite the histories of any other of our patients, but shall make those given above the basis for our comment

What possible explanation can there be for these remarkable postoperative results? We do not believe that the results were mere coincidences or that in the first patient we had to do with a case of multiple sclerosis in which, coincidently, a latent period of the disease had begun We have seen the effects described so often among more than 150 operations on the spine performed by one of us, that we have been forced to conclude that there was in our patients a direct connection between the laminectomy and the improvement We believe it possible that changes in the spinal circulation which follow a laminectomy may have a profound effect on early pathologic changes in the cord, and that the course of a spinal disease may be modified or halted by the operative interference We have not seen benefit in any patients in whom an exploratory operation exposed the conus and cauda equina This portion of the cord is very sensitive to changes in pressure, and bladder and rectal symptoms are so apt to occur as complications of the operation that an exploratory operation is justified only when strict indications for it exist In the cervical and dorsal regions, however, exploratory laminectomy may with less hesitation be performed in selected cases

CONCLUSIONS

1 The free removal of spinous processes and laminae with opening of the dura, in the absence of increased intradural pressure or a discoverable lesion,

---

[3] We are indebted to Dr Peterson for permission to report this case.

may be followed by a disappearance of normal cutaneous and tendon reflexes for a number of hours, or may be followed by the temporary return to the normal of pathologic reflexes

2 The operation of laminectomy may have a profound effect in certain pathologic states of the spinal cord and may so modify or check the disease that a return to normal conditions is even possible

3 On account of the relative safety of laminectomy in experienced hands, except in the region of the conus and cauda equina, and for the reasons stated above, exploratory operations should be done more often

TRICHINOSIS AND THE CEREBROSPINAL FLUID

WILLIAM LINTZ, M D
Professor of Bacteriology at the Long Island College Hospital, Associate Visiting Physician, Brooklyn Jewish Hospital
BROOKLYN

It is now over two years since I demonstrated for the first time the *Trichina spiralis* in the cerebrospinal fluid, in a patient suffering from trichinosis[1] I then expressed an opinion that perhaps lumbar puncture may become a useful method for diagnosing this disease My hopes were fully realized Before this procedure can be a real factor in the diagnosis of this malady, however, the parasites must be found in the cerebrospinal fluid (1) sufficiently early in the disease and (2) with a fair degree of constancy My findings of the *Trichina spiralis* in the cerebrospinal fluid have recently been confirmed by Leon Bloch, Young and others It is noteworthy that in Young's case the parasites were readily demonstrable in the cerebrospinal fluid but not in the muscle tissue

I wish to add three more cases in which I found the *Trichina spiralis* in the cerebrospinal fluid I am indebted to Dr Moshkowitz for the cerebrospinal fluid The patients were all Italians and ate pork infected with *Trichina spiralis* twenty-one days prior to the lumbar puncture The cases developed into typical cases of trichinosis and showed the usual subjective and objective symptoms of the disease, including the eosinophilia

In performing the lumbar puncture every precaution was taken not to introduce into the trochar parasites which may happen to lodge in the muscle of the back The trochar was introduced with its stilet, and the latter was withdrawn only after the trochar was successfully introduced into the cerebrospinal canal The cerebrospinal fluid was collected into sterile test tubes

In appearance the three fluids differed in no wise from that of normal cerebrospinal fluid They were perfectly clear and contained no sediments Chemically only one out of the three fluids failed to reduce Benedict's solution, all showed a faint trace of albumin and no increased amount of globulin The specimens were centrifuged, and the sediments showed but an occasional lymphocyte and from one to four trichinae per field These embryos were fairly motile and retained this activity to some extent at the end of three days when kept in the cerebrospinal fluid at room temperature These embryos are not in the least affected when placed in normal urine, and have no effect on red or white blood cells in suspension

Should the trichinae be found in the cerebrospinal fluid with a fair degree of constancy, this method clinches the diagnosis rapidly, as but few other single procedures do

1352 Carroll Street

A CASE OF TRICHINOSIS WITH EMBRYO IN THE SPINAL FLUID

W T Cummins, M D, and G R Carson, M D,
San Francisco

History—G F, man, aged 39, Greek, laborer, was admitted, Feb 27, 1916 Family and previous personal history were negligible January 22 he, together with five associates in the railroad section gang, ate some undercooked pork The present illness developed thirty-two days later with pains and soreness in the flexor muscles of the arms and the calves of the legs No history of initial abdominal pains and diarrhea could be elicited On admission the muscular pains had increased in severity and had involved the muscles of mastication Moderate frontal headache was present

Examination—The patient was well nourished and well-developed There was no jaundice Moderate periorbital edema was present The pupils were normal The tongue was red, moist and clean There was slight dulness and roughening of breath sounds at both apexes The heart and abdomen were normal The spleen was not enlarged Pressure over the biceps and leg muscles elicited well marked soreness Urinalysis revealed specific gravity, 1 024, acid, albumin trace, glucose negative, phosphates, no casts Blood pressure was 140 mm systolic, and 90 mm diastolic

Treatment and Course—After two or three days the periorbital edema disappeared, but the muscular pains and soreness increased, now involving the thighs and buttocks From time to time there was some general abdominal tenderness There was no diarrhea prior to the administration of purgatives At the end of the third week after admission the patient was much improved so that there remained only slight tenderness of the biceps, calves and thighs

Temperature, on admission, was 100 6, and for ten days maintained an average evening reading of 102, when it fell to normal and then maintained an average thereafter of 99 (The maximum temperature was 104) The pulse was disproportionately low with an average of 95 during the highest temperatures, likewise, respirations, 21

Castor oil, 2 fluidounces, was given on admission Calomel and magnesium sulphate were given at intervals of a few days Salol, 5 grains, was given three times a day Free catharsis was maintained

Laboratory Examinations—The *Trichina spiralis* was not found in the feces on one examination during the period of catharsis and well marked muscular pains Only venous blood was examined during the fourth week, following the technic of Staubli, and was negative At this time several specimens of sedimentized urine were examined and were likewise negative The parasite was demonstrated in large numbers in the gluteus maximus muscle in the fifth week of the disease when there were definite muscular pains and tenderness

On admission, the leukocyte count was 10,400, and rose to a maximum of 13,400 three days later The minimum count was 7,900, six days later The patient was discharged apparently well after thirty days in the hospital, the eighth week of the disease, with a leukocytosis of 9,600 and eosinophilia of 28 per cent The maximum eosinophilia was 53 per cent

The cerebrospinal fluid withdrawn during the fifth week of the disease showed after an exhaustive search of several sedimentized specimens one sluggishly motile embryo of characteristic appearance Its length was 0 1 mm, breadth, 0 006 mm The parasite in places appeared finely granular The oblique, clear band, described by Stäubli, between the anterior quarter and the posterior three quarters was not observed The motility was a slow, rhythmic bowing of the entire body with a bending of one end and then the other The spinal fluid was clear and under a moderately increased pressure Cells 3, globulin (ammonium sulphate and butyric acid) negative At this time there was no headache and all reflexes appeared normal The Kernig sign was negative.

---

[1] Van Cott, J M, and Lintz, William Trichinosis, The Journal A M A, Feb 28, 1914, p 680

COMMENT

Since in this case at the fifth week there were negative cytologic and chemical findings, and sluggish motility of the parasite, earlier examinations would appear advisable A routine spinal puncture (unless contraindicated) and neurologic examination of every trichinosis case may reveal much of interest in demonstrating the extent of parasitic migration into a hitherto unexplored field

Southern Pacific General Hospital

A CASE OF BETA-EUCAIN POISONING

T G Orr, M D Kansas City, Mo

The following case is reported from the Surgical Clinic of Dr M T Sudler, in the Bell Hospital, University of Kansas

A farmer, aged 60 admitted to the hospital for operation for double inguinal hernia and left hydrocele with negative family history and negative personal history except for occasional palpitation of the heart had had the left inguinal hernia for twenty-five years the right hernia for two years, and the left hydrocele for ten years

The patient was rather heavy and was healthy looking There were dilated venules on the face The right eye was artificial He had pyorrhea alveolaris The heart was irregular, with an extrasystole from every three to six beats The radial vessel walls were palpable The blood pressure was 160 There was a moderate cloud of albumin in the urine. There were double inguinal hernia and left hydrocele

On the day after admission under beta-eucain 0.25 per cent. anesthesia the Bassini operation for indirect inguinal hernia and operation for removal of the hydrocele sac were performed Twenty minutes before operation one-fourth grain of morphin was given hypodermically

The local anesthetic was administered in the usual way, and the hernia operation completed When the removal of the hydrocele sac was begun it was noticed that the patient had begun to perspire freely, and he soon began to complain of being tired When the patient left the table at 10 40 a m he was perspiring profusely and the skin had begun to feel clammy Respirations were now and then sighing in character The pulse was 88 and weak the respiration 20 and regular, except for interruptions by sighing At 11 30 the pulse was 84 and irregular the respiratory rate slow and irregular The venules of the face were much engorged The skin over the entire body was cold and clammy The pupils were contracted. Five minims of epinephrin chlorid were given in the vein which caused a transient increase in the strength of the pulse. The patient complained of pain in the head and abdomen At 12 o'clock it was impossible to feel the pulse, the respirations were of the Cheyne-Stokes type and at times there were intervals of almost a full minute without breathing Ten minims of epinephrin were then given, after which the pulse was 60 At 12 45 the pulse was 46 One one-hundredth grain of atropin was then given hypodermically One thousand cubic centimeters of saline were given intravenously with 15 minims of epinephrin At 5 30 p m the pulse was 46, and the patient's general condition somewhat improved though he complained of numbness of the left hand and foot At 7 p m he was more comfortable his pulse 64 At 8 30 p m. the pulse was 74 the respirations still of the Cheyne-Stokes type but the period of complete cessation of breathing was not longer than fifteen seconds At 10 p m., almost twelve hours after the onset of toxic symptoms, the pulse was 76 and of good quality and the respirations were 20 and regular The next day he had apparently completely recovered

The patient's improvement was uneventful until the fifth day after the operation, when at 2 o'clock in the morning, in the absence of the nurse, he sat up in bed to take a drink of water, and dropped back on his pillow dead The necropsy showed an embolus in the left coronary artery

The quantity of beta-eucain used in this case did not exceed 3 ounces of a 0.25 per cent solution Three ounces was the quantity placed on the instrument table for use If all of the solution had been injected into the tissues the quantity of the drug would amount to 3 4 grains When waste is considered, it is highly improbable that so much was actually absorbed by the tissues

Hertzler[1] states that beta-eucain may be used in quantities up to 3 grams, it is said, and as much as 15 grains have been used without alarming effects" Barker[2] reports the use of as much as 6 ounces of a 0 2 per cent solution of beta-eucain in a goiter operation without toxic effect M T Sudler has used as much as 5 ounces without causing any symptoms of intoxication

In a hurried review of the literature, I have found reference to six cases of intoxication due to beta eucain Way[3] reports a case of poisoning while doing a circumcision In his case, less than 2 grains were used Kraus[4] describes a case of poisoning from injecting 10 c c of a 2 per cent solution into a urethra the day following an internal urethrotomy, which caused very distressing toxic symptoms In the same article he refers to two cases reported by Marcinowski, one by Dolbeau, and one by Simon In one of Marcinowski's cases only a transient syncope was noted, and the patient was subject to fainting attacks In the other case after injection of 1 5 c c of a 10 per cent solution, the patient exhibited tonic and clonic spasms which gradually subsided after fifteen minutes, but were followed by stupor and weakness, the symptoms all passing away by the end of six hours Dolbeau's case was caused by the intravenous injection of the drug The case reported by Simon was characterized by transient headache and vomiting in a man whose bladder had been filled with 80 c c of a 4 per cent. solution for a Bottini operation

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK 'NEW AND NONOFFICIAL REMEDIES'

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL

W A PUCKNER, SECRETARY

GLYCOTAURO (See N N R., 1916, p 61)
The following dosage form has been accepted

Enteric Coated Glycotauro Tablets—Each tablet contains glycotauro 2 grains and is coated with salol. Prepared by Hynson Westcott & Co Baltimore Md

PETROAGAR—Each 100 grams contains petrolatum 0 72, agar 0.22, with powdered licorice, cocoa and oil of anise sufficient to flavor U S trademark applied for

(Accepted for inclusion with the appendix to New and Nonofficial Remedies.)

Prepared by H C Merker Co, Chicago Ill.

PETROBRAN—Each 100 grams contains petrolatum 0.74 bran 0.22, with powdered licorice and "oil of pineapple (ethyl butyrate) sufficient to flavor U S trademark applied for

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by H C. Merker Co Chicago Ill.

THE FUNCTION OF THE OMENTUM IN PERITONEAL ABSORPTION

That substances in solution can be absorbed through the direct intermediation of the blood vessels from connective tissue interstices as well as from the larger spaces, such as the pleural and peritoneal cavities, has long been demonstrated beyond a doubt There was a time when it was assumed with considerable confidence that the drainage from such tissue spaces is essentially a function of the lymphatics arising from them It shall not be denied that the lymphatic circulation, sometimes even spoken of as the "absorbent system," may take part in this process of absorption But the process of lymphatic absorption, even when aided by active or passive movements, is a comparatively slow one and will scarcely suffice to explain the rapidity with which a poison in solution can be removed from a tissue space and distributed in the body so as to exert its toxic action after a brief interval When colored solutions are introduced into the peritoneal cavity, the dyestuff appears in the urine long before a trace of it can be detected in the lymph flowing from the thoracic duct Absorption and manifestations of the distribution of the substance taken up can be demonstrated even when the lymph is conducted to the exterior of the body or when its channels are obstructed In all such cases, then, the conclusion seems inevitable that absorption is by the blood vessels, and consists in an interchange between the circulating fluid of the vascular system and the extravascular medium

It has not been equally easy to explain the removal of particles, such as micro-organisms or foreign precipitated matter, from the larger tissue spaces Here, at any rate, it has seemed necessary to postulate the prominent cooperation of the lymphatics Thus studies on the mechanism of removal of granules from the peritoneal cavity have indicated the participation of the diaphragmatic lymphatics as the channel through which suspended particles reach the lymph glands, where they are commonly deposited The existence of peculiar stomata in the diaphragm has been debated, so that it has been necessary to relate the transport of suspended particles to the activity of migratory macrophages

Shipley and Cunningham,[1] of the anatomic laboratory at the Johns Hopkins University, have pointed out that the question of the omentum's share in ridding the peritoneal cavity of foreign substances has generally been evaded They state that those authors who admit the possibilities of the omentum as an absorptive pathway are unanimous in the belief that absorption of granules takes place by way of the omental lymphatics In the absence of definite knowledge of the facts of the case, they add, such a conclusion as regards the absorption of particulate matter is logical when we consider the part which lymphatic radicles play in the removal of granules from any locality, and the ease with which granular material injected into the peritoneal cavity may be recovered from the lymphatic glands It is by no means certain, however, that there are any lymphatics in the omentum at all

It is obviously not easy to establish the special role of the omentum as a seat of absorption because of the ease with which foreign matter in solutions and suspensions brought into contact with it can find its way to nearby absorbing surfaces Shipley and Cunningham have succeeded, however, in conducting experiments satisfactorily by withdrawing the omentum from the body cavity through a midline incision and keeping it immersed, under physiologic conditions, outside of the cavity in fluids which it was desired to study Possible participation of lymphatics, if such there are, was excluded by ligation of the thoracic duct Without giving the details of this novel investigation, it can be stated that true and pseudo solutions and granules of particulate material find their way through omental vessels to the organs of the body destined for their ultimate reception and storage or destruction and excretion, and the path by which they leave the omentum is not a lymphatic but a hemic one The Baltimore investigators further remark that the drainage of particulate matter from the serous cavities by way of the blood stream is most extraordinary, and was most unexpected since the blood vessel wall is not credited with permitting the passage of anything but fluids with a possible exception in the capillaries of the intestinal mucosa Lymphatic vessels could not be discovered in the omentum, and if they do exist they need play no important part in the actual drainage of the surrounding tissue space It is confidently believed that a considerable amount of granular material may leave the cavity of the peritoneum through the omental veins, though the limits of granular size and the mechanism of transit have not yet been ascertained

CHROMOPHIL TISSUE AND EPINEPHRIN

The suprarenal capsules of mammals consist of two parts, the cortex and medulla. With the latter of these structures the presence of epinephrin is associated. There are various other evidences that the cortical and medullary portions of the suprarenals represent distinct tissues differing in function. Portions of the medulla stain darkly with chromates, hence the designation of chromaffin or chromophil substance has been applied to the areas involved. Chromaffin tissue is found in various situations throughout the vertebrate kingdom. In some invertebrates chromaffin nerve cells occur. This has raised the question as to whether the production of the potent epinephrin is a characteristic of chromaffin tissues wherever it may be found, so that the histologic demonstration of the latter would be an indication of the occurrence of a substance having the unique pharmacodynamic action of the "active principle" of the suprarenal medulla.

The evidence of a common origin and similar physiologic effect of such tissues with similar staining reactions is accumulating. In some fishes the two portions of the suprarenal gland remain separated throughout life, the cortex being represented by a series of paired interrenal bodies lying on the front of the spinal column, and the medulla by a number of collections of chromaffin cells lying in close juxtaposition to the spinal nerves. Extracts of these chromaffin tissues behave like those of the suprarenal medulla when they are injected into the blood stream. The same is true of the masses of tissue found in close association with the sympathetic system, which present the chromaffin reaction typical of the medulla.

The most recent investigations in support of the provisional assumption that chromophil tissues are specific in their nature, and everywhere of the same essential character, relate to the retroperitoneal tissues in man and other animals. Fulk and Macleod,[1] of the physiologic laboratory at the Western Reserve University, have repeated earlier experiments of Biedl and Weisel indicative of the presence of an epinephrin-like constituent. By the use of the most recent technic involving the physiologic action of suspected extracts on intestinal and uterine muscle, the pharmacologic identity of the chromophil tissue has been further established.[2]

In view of the apparent connection between chromaffin nerve cells and those of the medulla of the suprarenal bodies, and the relation between the action of epinephrin and that of the sympathetic system, J. F. Gaskell[3] has suggested a possible interrelation. He imagines that the chromaffin nerve cells of the invertebrate are the common ancestors of the epinephrin-secreting chromaffin system and the sympathetic nervous system of the vertebrate. Thus we find the contractile vascular system regulated both by the sympathetic nerves and by the secretion of epinephrin.

THE NATIONAL DEFENSE BILL AND THE ARMY MEDICAL SERVICE

The national defense bill, signed by the president, June 3, fixes the proportion of medical officers at seven to each thousand of the enlisted strength of the army. This proportion, which existed at the outbreak of the Spanish War and was again restored in 1908, has been seriously reduced through gradual increase of the army, until the enlisted strength had grown 35 per cent. without the addition of a single medical officer.

The new law provides for a definite ratio rather than for a fixed number of medical officers. This will automatically prevent any changes in the ratio in the future. The period of service required of medical officers before promotion to the grade of captain has been increased from three to five years. The medical reserve corps is abolished one year after the passage of the act. Officers of the reserve corps may be appointed to the medical section of the officers' reserve corps, in which body commissions may be issued in three grades — lieutenant, captain and major. Officers of the dental corps are open to promotion to the grades of captain after eight years' service, and to that of major after twenty-four years' service, subject to the same examination conditions as obtain in the medical corps. Veterinary surgeons of the army are formed into a separate corps attached to the medical department, and are given promotion to the grade of major. The hospital corps is hereafter to be known as the enlisted branch of the medical department, and several new grades, such as master hospital sergeant and hospital sergeant, are created. Through a reduction in the proportion of privates first class in this department, the pay of 75 per cent. of the enlisted men in the medical service will be reduced from $18 to $16 a month. As the care of the sick is not particularly attractive work to the ordinary soldier, this reduction will probably increase the difficulty of obtaining recruits of fit character and intelligence for the medical service. The new law does not provide any promotion for medical officers above the grade of colonel, except the single position of Surgeon-General of the Army. Provision is made for the assignment of five officers of the medical corps for duty with the medical relief department of the Red Cross, and the erection of storehouses by the Red Cross on military reservations or the use of government buildings as such storehouses.

The new law is highly satisfactory in that it establishes a permanent ratio between medical men and enlisted men, provides for an efficient medical reserve, raises the standard of dental and veterinary surgeons, and improves conditions regarding promotion and grade It is unsatisfactory in that it reduces the pay of enlisted men in the medical corps and so increases the difficulty of securing satisfactory nurses and attendants in military hospitals This defect, however, can readily be remedied by later amendment

DIET AND METABOLISM IN CHRONIC INTERSTITIAL NEPHRITIS

It is a significant and fortunate circumstance that increased attention is being directed to the establishment of a rational basis for dietotherapy in many forms of chronic diseases Customs of feeding and textbook admonitions are handed down from decade to decade, often involving systems or details of diet that are as unnecessary or ineffective as they may be irksome to the patient A basis for the critical consideration of this has recently been furnished from the medical clinic of the Johns Hopkins Hospital by Mosenthal and Richards[1] There is much diversity of belief and of practice regarding the amount of protein, and particularly of meat, which may be allowed to the chronic nephritic In cases of the interstitial type, with which alone we are here concerned, it is frequently stated by clinicians of experience that the danger of the retention of waste products in the organism without elimination by the usual renal channel is always a serious one Thus Strauss[2] raises the question whether the familiar polyuria is not to be interpreted as an "antiuremic" response, so that the restriction of fluids advocated by some in the management of the disease presents the added danger of intoxication from uneliminated poisons

As a scientific basis for the supposed perversion of protein metabolism, it has been pointed out that when the food intake and urinary and fecal outputs are carefully measured, a gain of nitrogen to the body is not infrequently discovered Storage of nitrogen is, of course, not a common or long protracted phenomenon in man except during the period of growth or during the convalescence from depleting disease, yet ordinarily one would hesitate to charge a positive nitrogen balance of this sort in a patient only moderately well nourished to any abnormality of metabolism unless the gain were so large as to become unduly conspicuous Students of the metabolism of nephritis have nevertheless interpreted positive nitrogen balances in individuals with interstitial disease as indicative of abnormal retention, that is, they have assumed that the kidneys are insufficient and that consequently the urinary nitrogen cannot keep pace with the quantity ingested Mosenthal and Richards[1] have put patients with chronic interstitial nephritis of moderate severity on "low protein" diet and subsequently on "high protein" diet in order to control some of the factors just discussed With daily nitrogen intakes ranging from 16 gm to as high as 47 gm they observed a positive nitrogen balance, as other investigators likewise have done Shall it be assumed from this, as has heretofore usually happened, that the retained nitrogen circulates in the body as nonprotein nitrogen and manifests itself by a rise in its concentration in the blood? Here the newer methods of blood analysis afford a helpful solution to the question It was calculated that the ingested nitrogen unaccounted for in the excreta would suffice, in the different cases investigated, to raise the nonprotein nitrogen of the blood of these patients to calculated values ranging from 78 to 148 mg per hundred c c of blood, yet the actual values in no instance exceeded 38 mg Mosenthal and Richards remark that even an extremely large error in their theoretical calculations would not invalidate the conclusion that the retained nitrogen was not circulating as waste nitrogen, but had been assimilated or stored by the body tissues

A similar storage may occur in normal individuals on a high calory diet It is therefore misleading to regard these retentions as an index of inability on the part of the kidneys to eliminate nitrogen If it were such, then there must be compensatory action on the part of some cellular tissue or other which prevents the appearance of the excess in the blood as waste nitrogen Mosenthal and Richards cautiously conclude that until these phenomena are elucidated, discretion must be exercised in interpreting a normal figure for nonprotein nitrogen of the blood as indicating that no nitrogen retention has taken place, likewise in considering a positive nitrogen balance as an absolute indication of the inability of the kidney to excrete this substance It is almost needless to add that the ultimate solution of a suitable and theoretically defensible diet in such forms of nephritis must await the answer to the problems of intermediary metabolism which center in the disease Perhaps one can already foresee a possible outcome in the apparent reaction against a too strict enforcement of the no-meat rule in nephritis

---

Suprarenal Theory of Pellagra—M P Modinos is convinced that pellagra is the result of defective functioning of the endocrine glands, especially the suprarenals The sympathetic system suffers in consequence, and this might cause all the symptoms of pellagra He practices in Egypt, where pellagra is not very common The three cases of pellagra that have come under his charge apparently sustain his assertions, as two of the patients recovered completely under systematic suprarenal treatment The third patient succumbed to a concomitant liver abscess, and the suprarenals were found double the normal size, hard and purple His report appeared in the *Bulletins Soc Med des Hop de Paris,* April 6, 1916, p 440

TRIPLE MERGER OF MEDICAL COLLEGES IN PHILADELPHIA

A noteworthy merger of medical colleges has just taken place in Philadelphia, by which the Medico-Chirurgical College, the Jefferson Medical College and the University of Pennsylvania, School of Medicine, have united to form one larger teaching institution The Medico-Chirurgical College is to be the graduate school of medicine of the University of Pennsylvania, its corporate title to be ' The Medico-Chirurgical College and Hospital, Graduate School in Medicine of the University of Pennsylvania " The Jefferson Medical College and the University of Pennsylvania, School of Medicine, will continue undergraduate medical teaching under a joint title, although retaining their individual identities so far as their properties and endowments are concerned The union of these three institutions, therefore, will provide not only for the better instruction of undergraduates but also for the development on a high plane of instruction for graduates The plan under which the Jefferson Medical College and the University of Pennsylvania, School of Medicine, have been merged is given on another page[1] Since the University of Pennsylvania has recently found it necessary to limit the enrolment of medical students, the union with the Jefferson Medical College is opportune, and will provide the additional teachers, laboratories and clinical material by which larger numbers of medical students can be cared for This merger provides a single management, a single curriculum and single standards for the admission, promotion and graduation of students It also permits a single control, and, therefore, a more systematic and efficient use of the abundance of clinical material formerly controlled by three separate institutions This merger marks a decisive step forward in medical education in this country, and will doubtless point the way to future mergers in other cities

THE QUESTION OF SECRETORY NERVES FOR THE KIDNEY

The secretory activity of the kidney is so closely bound up with its blood supply, which in turn is so susceptible to regulatory impulses transmitted to it through the vagus or the splanchnic nerves, that the problem of the existence of specific secretory nerves for this organ has not been adequately answered The vacillating views have been referred to from time to time in THE JOURNAL[2] The supposedly positive findings were based on the outcome of changes in the water output of the kidneys after experimentation on the vagus and splanchnic innervation One of these nerve groups was believed to carry secretory, the other inhibitory fibers The failure to obtain evidence of any increased cellular metabolism which might be indicated in an increased gaseous exchange in the kidney as the result of nerve stimulation has led in turn to doubts regarding the existence of the secretory fibers believed by Asher to exist A different sort of evidence has been furnished by Quinby[3] of the Johns Hopkins Hospital By means of vascular suture he has removed the dog's kidney from the body and later restored it to its former position Such a kidney is removed from the control of the nervous system, for a time at least Examination of the renal function shows an initial period of overaction, as compared with that of the normal organ This is followed by a balanced action Evidence has now been furnished that a single implanted kidney is able to maintain normal life Though the results throw no direct evidence on any possible secretory function of either the vagus or the splanchnic nerves, they suggest strongly that secretory nerves, if they exist, must play a minor part in renal secretion No lack of their action is indicated in Quinby's experiments When it is recalled that the existence of diuretics derived from special tissues in the body has been postulated of late, it becomes probable, quoting Quinby, that vasomotor conditions of the kidney, added to the chemical and hormone action of substances contained in the circulating blood, will be found entirely adequate to explain all the variations and types of normal renal function

REINFECTION IN SYPHILIS

The question as to the possibility of the occurrence of more than one infection with the *Spirochaeta pallida* has always been a live one Formerly syphilographers generally believed that cases of reinfection in this disease were exceedingly rare, some going so far as to deny their possibility With the general adoption of more prolonged and vigorous treatment, however and particularly with the recent advent of salvarsan, it has seemed probable that these views are subject to modification The protean aspect of syphilitic lesions always renders their recognition on clinical grounds alone open to considerable question For this reason the cases reported by some of the older writers, and particularly those occurring in the presence of obvious tertiary lesions, most likely represent recrudescences rather than true reinfections Lately, however, particularly during the last year or so, many reports have appeared in the literature of apparently well authenticated cases of a second, and a few of even a third and fourth infection Many of these cases have been studied both parasitologically and serologically Those patients who give a history of a previous chancre, or have been examined at the time of their infection and have had a positive Wassermann reaction which has disappeared on treatment, who again evince the clinical manifestations of a primary infection in which the *Spirochaeta pallida* is demonstrated, and who subsequently develop a second positive Wassermann, apparently present cases of true reinfection In the absence of an absolute means of determining when a cure is final and complete, however, there is even in some of these cases a possibility that it concerns a recrudescence of a previous infection rather than a reinfection, the weak point in many of the reports being the very short time between the first and second infections Nevertheless the repeated occurrence of such cases tends to indicate that the present methods of treatment, if accurately carried out, are capable of eradicating syphilitic infection, and from this point of view true syphilitic reinfection may be regarded as encouraging evidence of the efficacy of the treatment

COTTAGE SCHOOLS

The *Weekly Bulletin* of the New York City Department of Health calls attention to an article by Todd[1] urging the replacement of the present style of "tenement" schools by buildings erected on the cottage plan In favor of this plan is the reduction of risk from infectious disease, particularly so far as such risk is due to the mingling of children from different rooms in the halls of the large buildings Todd considers the ground necessary for the cottage school plan one of its chief assets Much is to be said in favor of the idea that school buildings are a poor financial investment and that a simpler and cheaper as well as more hygienic style of construction would be preferable The one story cottage school almost entirely eliminates danger from fire, especially when proper material is used in its construction The elimination of stairs and basement increases sanitary merits and decreases the cost of construction The elimination of elaborate and expensive ventilating systems also cuts down operating cost

FRAUDULENT ADVERTISING IN THE DISTRICT OF COLUMBIA

Congress prohibits fraudulent advertising in the District of Columbia Why not within the entire federal jurisdiction? Congress has passed a bill, which was signed, May 29, by the president, prohibiting "fraudulent" advertising in the District of Columbia By this act it is made unlawful to display or exhibit to the public in any manner whatever, whether by handbill, placard, poster, picture, film or otherwise, or to insert or to cause to be inserted in any newspaper, magazine or other publication printed in the District of Columbia, or to issue, exhibit or in any way distribute or disseminate to the public, or to deliver, exhibit, mail or send to any person, firm, association or corporation any false, untrue or misleading statement, representation or advertisement, with intent to sell, barter or exchange any goods, wares or anything of value The act further prohibits the use of any of the methods of advertising described above with the intent or purpose to deceive, mislead or induce any person, firm or corporation into employing the services of the advertiser The House of Representatives committee report on the [illegible]ll expressly states that it is designed, among other things, to prevent quack doctors and fake dentists from advertising their fraudulent nostrums, impossible methods and alleged results If the president and Congress agree that a law to prevent fraudulent advertising is a good thing for the District of Columbia, will they not agree that a similar law would be equally good for interstate and foreign commerce and for the purification of the United States mails?

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Personal—Dr Frank A Stubblefield has been transferred from the staff of the Alton State Hospital to that of the State Hospital for the Criminal Insane, Chester He has been succeeded at Alton by Dr Van Pelt

Typhoid Dangers—The state board of health reports that Pana, Christian County, and Tuscola, Douglas County, are menaced by an epidemic of typhoid At Pana there are thirty-eight clearly defined cases of the disease and at Tuscola fifteen cases have been reported Sanitary inspectors are at work endeavoring to ascertain the cause of the epidemic

Chicago

Memorial for Dr Favill—A committee has been organized to establish a memorial to Henry Baird Favill under the auspices of the City Club and Commercial Club Drs Frank Billings and Emilius C Dudley are the medical members of this committee, which hopes to receive subscriptions amounting to $250,000

Surgical Society Election—At the annual meeting of the Chicago Surgical Society, June 2, the following officers were elected president, Dr William M Harsa, vice president, Dr William Fuller, secretary, Dr Kellogg Speed, and treasurer, Dr Frederick G Dyas

Mercy Hospital Wing Completed—The completion of the new $300,000 addition to Mercy Hospital was announced, June 4, and the formal opening of the building will take place June 15 The new building is four stories in height, and is designed especially for the care of sick children The outstanding indebtedness of the institution now amounts to more than $200,000, and the opening of the building will mark the beginning of a campaign to raise funds to wipe out this deficit

MARYLAND

Transfer of Quarantine—An ordinance authorizing the transfer of quarantine from the city of Baltimore to the federal government was introduced in the second branch of the Baltimore city council, May 22, and was referred to the committee on health

Survey at Frederick.—A medical survey of Frederick is being made by officials of the United States Public Health Service, working in cooperation with the Franklin County officials, the secretary of the state board of health and Dr William W Ford, professor of bacteriology in Johns Hopkins University

University of Maryland Alumni and Graduation Banquet.—The first alumni and graduation banquet of the medical and the general alumni association of the University of Maryland was held, May 31, at the Emerson, and was attended by over 500 alumni and graduates The following officers of the general alumni were elected president, E John W Revell, vice president, Dr Albert H Carroll, treasurer, William Stichel, recording secretary, Dr F V Rhodes, corresponding secretary, Edward P Crummer, and advisory council, medical Drs Charles E Sadtler, Arthur M Shipley and James M H Rowland

Personal—Dr Eugene W Heyde, Parkton, has been appointed one of the health officers of Baltimore County to fill the vacancy caused by the death of Dr Joseph S Baldwin,

  jacketed surgical experiences with, [Bogdanik] (78) 541
  Localization of See under Foreign Body
  lodged in tissues, [Witzel] (86) 1750
  pointed small caliber action of as observed during Balkan war [Kochetoff] (99) 231
  thoracotomy for removal of shell fragments and from diaphragm lungs or pericardium, [Mintz] (92) 391
  Wound See Wound Gunshot
BUNGPAGGA disease of gold coast called preliminary note [Patton] (18) 1494
BUNIONS plasterers corns and, [Boehme] (81) 1167
BUREAU of Mines and first aid movement [Clough] 1263—C
BURNETT E J information wanted regarding 1210
BURNS bicarbonate of soda in [von Wedel] (108) 1745
  ferric chlorid in, [Slack] (54) 1166
  from hot-water bag damages allowed for 1162—Ml
  from light balls, 4 cases [Goebel] (47) 694
  received during operation, liability of surgeon for 212—Ml
  Roentgen ray literature on 1156
  treatment of [de Tarnowsky] (66) 1166 [Brown] (86) 1354
BURSITIS subacromial [Brickner] 912—C [Montgomery] 1051—C
  subacromial and concretions cases of [Plummer] (109) 1583
  subacromial deposit in supraspinatus muscle simulating, [Dunlop] (19) 689
  subdeltoid with deposition of lime salts [Montgomery] *264
  syphilitic, involving both knees [Scott] (7) 982
BUTTER fat, growth promoting substance in stability of, [Osborne] (58) 533
BUTTNER, death of typhus investigator 826

BOOK NOTICES

Adolescent Period 835
Albee F H Bone Graft Surgery, 1053
Allbut C, Diseases of the Arteries Including Angina Pectoris 451
American Encyclopedia and Dictionary of Ophthalmology, 1488
Amino Acids, Physiology of the 378
Amoss, H L, Text-Book of Chemistry and Chemical Uranalysis for Nurses, 53
Anatomy Clinical of the Gastro Intestinal Tract 52
Arrhenius, S Quantitative Laws in Biological Chemistry, 378
Arteries, Diseases of the Including Angina Pectoris, 451
Augenheilkunde, Geschichte der 914
Baby's First Two Years 139
Bacteriology, Introduction to, for Nurses 1269
Bandaging, 378
Barton W M, Manual of Vital Function Testing Methods and Their Interpretation 1577
Billings, F, General Medicine, 1421
Bing R, Text-Book of Nervous Diseases for Students and Practicing Physicians 1159
Bloodletting, Theory and Practice of, 594
Blood Vessels, Surgery of the 594
Blumer G A, Institutional Care of the Insane in the United States and Canada 1882
Bone Graft Surgery, 1053
Bradford, E H, Orthopedic Surgery, 835
Brophy, T W, Oral Surgery, 980
Brown L Rules for Recovery from Pulmonary Tuberculosis, Layman's Handbook on Treatment, 378
Buchanan, R J M Text-Book of Forensic Medicine and Toxicology, 53
Buck M M C, and Hall, H J, The Work of Our Hands 1054
Burgess T J W, Institutional Care of the Insane in the United States and Canada, 1882
Cancer Mortality from Throughout the World, 2028
Carey, H W, Introduction to Bacteriology for Nurses 1269
Chapin, H D, Diseases of Infants and Children 139
Character and Temperament 451
Chartres, A V, Marie Tarnowska, 451
Chemistry and Chemical Uranalysis for Nurses Text-Book 53
Chemistry, Physiological Text Book and Manual for Students, 300
Chemistry, Quantitative Laws in Biological, 378
Children and Infants Diseases of, 139
Circulation in Health and Disease Modern Aspects of 678
Colloid-Chemistry, Handbook of, 531
Colon Hygiene 1813
Crile G W, Mechanistic View of War and Peace 980
Curtis J G, Harvey's Views on the Use of the Circulation of the Blood, 2028

left in abdomen and in surgical wounds, [Mann] (142) 149
localization of [Desgouttes] (63) 152 [Cadenat] (58) 988, [Ghilarducci] (104) 1360
localization of compass technic for [Desplas] (39) 66
localization of during removal improved technic for [Schwarz] (74) 610
localization of in tissues [Bey] (67) 1064 [Mahar] (33) 1277, [Desplats] (41) 1894
localization of metal in tissues, [Gocht] (65) 1278
localization of *new apparatus for,* [Hallam] (4) 310
lungs extraction of projectiles *lodged in 1037, [Villéon] (22)* 1356
magnet extraction of [Smith] *(104) 986*
metal geometrical formula to locate with Roentgen rays [Charlier] (37) 537
nonmagnetic steel instruments for removing 1935
nose removal of knife blade from symptoms and results, [Vaughn] (142) 1060
orbit [Miller] (133) 1660
orbit weighing 56 grams, [Dauthuile] (27) 1356
orientation method of locating projectiles in tissues [Kunz] (115) 155
pericardium bullet causing no disturbance [Müller] (79) 1359
pericardium bullet removed from report of case [Lower] (9) 1888
pericardium or heart extraction of [Couteaud] (32) 226
pleura fragment of shell in extraction of with magnet [Burk] (28) 1432
pneumonias [Caillé] (33) 532
projectiles embedded in bone hook in extraction of, [Imbert] (48) 1586
projectiles search for and removal of [Schwenk] (53) 66
rectum [Falk] (63) 67 [Eliot] (147) 605
respiratory passages of children clinical findings of [Price] (149) 310
respiratory tract in war [Ferreri] (114) 1282
Roentgen localization of [Stansfield] (29) 150 [Neumann] (78) 314 [Albers Schönberg] (41) 388, *[Seubert]* (106) 610 [Schmerz] (99) 779 [Strohl] [Ghilarducci] (90) 696 (43) 925 [Weil] (54) 925 [Grashey] (100) 928 [Hammes] (50) 1357 [Holzknecht] (60) 1664 [Barclay] (1) 1746, [Andrault] (77) 1826
stomach résumé on [Amerson] (30) 1820
swallowed by insane woman [Balfour] *421
swallowed *by patients* [Landrum] (153) 1660
swallowed 5 teaspoons removed from *intra abdominal* abscess after perforating small intestine [Tilton] (114) 63
thorax and abdomen localization of, [Rautenkrantz] (94) 1359

FOREIGN BODY thorax extraction of projectiles from 12 cases [Mintz] (52) 1434
thorax localization and removal of [Beck] 217—ab
throat of infant 3½ months old [Robertson] (94) 1275
tongue scrap of shell in without reaction [Ferrand] (36) [illegible]
urinary bladder [Judd] 218—ab
urinary bladder value of lithotrite in removing [Owre] (40) 603
FOREMAN power of to contract and receive notice as to needed medical aid for employee 764—Ml
FORESTRY and public health [Hopkins] (77) 1333
FORMALDEHYD metallic antimony and antimonyl sodium tartrate in kala azar [Brachmachari] (20) 843
tetanus toxin treated with immunization with [v Eisler] (99) 315
vapor method in Lange s colloidal gold test [Hulbert] (94) 708

abuse of sling [Lochard] (40) 1748
acetabulum case of [Borden] (99) 2041
and fracture dislocations [McArdle] (24) 2127
ankle compound splint for [Sinclair] ( ) 842
apparatus for continuous extension in [Mouls] (55) 1586
arm compound splint for [Giles] (7) 150
arm or thigh compound first dressing for [Brix] (38) 389
arm or thigh quickly improvised splints for [Busalla] (74) 713
arm portable extension appliance for [Frank] (70) 1750
arm treatment of in war [v Lesser] (89) 1280
arm upper and shoulder treatment of [Schlesinger] (108) 611
arm upper and thigh infected later care of [Menne] (106) 779
arm upper extension with triangular support for [Burk] (57) 228
arm upper plaster cast for [Anker] (64) 539 [Oelsner] (101) 541
artificial leverage in reduction of, [Clifford] (129) 605
astragalus [Baudet] (51) 538
astragalus and isolated dislocation after grenade contusion [Harf] (44) 388
axis nonfatal [O Brien] (27) 457
bone grafts autogenous in nonunion and malposition of of long bones [Goldsmith] (43) 840
bone peg in heterogeneous intramedullary possibilities and limitations [de Tarnowsky] (121) 1746
bone transplant in [Morton] (112) 536
calcaneum as typical injury on man of war [Magnus] (94) 610
callus structure after therapeutic indications from [Wachtel] (107) 155
capitellum [McCampbell] (126) 1275
clavicle immobilized with rod passed through bend of elbows behind back [Lüthi] (71) 1587
clavicle treatment of [Konosevitch] (124) 850
Colles [Robertson] (82) 691 [Reeves] (26) 1272
Colles and Pott s bad results of [Eve] (140) 605
comminuted management of [Merriel] (51) 776
compound bridge plaster casts for in war [Sénéchal] (46) 462
dislocation of cervical vertebrae [Bradburn] (136) 224
dislocation of elbow chronic progressive neuritis following [Hunt] *11
elbow [Grossman] (85) 459 [McCarty] (66) 841
femur [Rummel] (85) 314
femur and injury of spinal cord apparatus for extension with [Partos] (105) 154
FRACTURES femur artificial impaction of [Cotton] (37) 984
femur care of [Werndorff] (107) [illegible]
femur compound combined apparatus for [Cruet] (41) 988
femur compound interrupted hammock bed in [Bryan] (17) 460
femur extension treatment of [Kaufmann] (34) 1855
femur extreme movability of hip joint after healing of [Küttner] (91) 1589
femur first measures for [v Haberer] (105) 848
femur gunshot and shell treatment of [Danziger] (30) 1589
femur management of in war [v Stubenrauch] (91) 1770
femur neck of [McClennan] (114) 1059
femur splint for [v Cergö] (117) 543
femur treatment of with Steinmann nail [Depping] (142) 1355
femur walking extension apparatus for improved technic for [Lamare] (79) 173
fistulas persisting after [Janssen] (69) 1664
fixation of fragments after metal plates to aid in [Villard] (34) 1747
gunshot extension and bridge plaster dressings for [Shamarin] (114) 1761
gunshot of extremities [Greenough] (40) 383
gunshot of long bones [Simmons] (12) 770
gunshot treatment [Groves] (20) 1854
gunshot treatment by external fixation apparatus [Simmonds] (16) 1494
hyoid bone greater cornu of from muscular action [Vine] *1618
hyoid bone report of case [Hull] (113) 921
humerus aluminum splint for [Mackenzie] (4) 1431
humerus shaft of ununited bone transplantation in [Henderson] (59) 1429
immediate reduction of plea for [Darrach] (15) 1888
in tabes spontaneous of bones of foot [Roubier] (43) 1662
in young infants treatment of [Buchheim] (45) 389
jaw dentistry methods applied in treatment of [Bjerrum] (135) 780

skull grazing, causing motor aphasia and loss of memory trephining, recovery, [Müller] (92) 1359
skull later course of [Hayward] (47) 844
skull operative treatment for [Gayet] (39) 461 [Ehrenpreis] (37) 1357 [Allen] (116) 1659
skull penetrating treatment of [Sargent] (8) 986
skull, removing splinters of bone after abscesses in brain and, [Perthes] (97) 991
skull septic meningitis from, followed by aseptic suppurative meningitis, recovery, [Pollcard] (52) 1171
sodium perborate in, [Bourgeois] (52) 1662
spastic affections of spinal cord from, radiotherapy in, [Bonnus] (44) 538
speech disturbances following in war, treatment of, [Froschels] (73) 313
spine of warfare, [Holmes] (12) 149
spleen, [Delore] (70) 1172
spleen stab, [Kollas] (116) 1282
stab, suprapubic technic for making, [Reder] *272
sterilization of and immediate closing, [Carrel] (37) 775
sterilization of skin and iodin fumes for [Bulling] (116) 155
stomach, fatal without operative treatment, [Böhler] (56) 228
sugar for dressing, advantages of [Meyer] (115) 779
sympathetic nerves and vessels, [Meige] (59) 1587
talipes equinus following decapitation of astragalus to correct, [de Fortunet] (45) 607
tendons incised treatment of [Dorrance] 1734—C
testicles, treatment of, [Levy] (71) 1064
tethelin in healing of [Robertson] *1009
WOUNDS, thigh lacerated hypochlorous acid in, [Miles] (14) 842
thorax, [Piéry] (42) 1748, [Mallet] (35) 1894
thorax and lungs, [Lonhard] (78) 777
thorax, operative treatment of in war, [Gasquet] (48) 1748
thorax, physical signs and symptoms of, [Howard] 2030—ab
thorax pleurisy after in war [Gerhardt] (90) 990
thorax spontaneous evolution and treatment of, [Thévenot] (69) 152
thorax sputum with old, [Loeper] (75) 1826
thorax streptococcus and other complications of [Martin] (44) 1586
thorax treatment of, [Hofbauer] (25) 1432, 1562
throat, [Ferreri] (115) 849
torpid treatment of [Debat] (47) 1895
tracheobronchial glandular lesions mistaken for projectiles, [Weil] (32) 694
treatment of in war [Munroe] (39) 147 [Soubeyran] (30) 311, 442, [Treiber] (70) 846 [Cheyne] (6) 986, [Saint] (5) 1276
trophic disturbances with affecting nerves of limbs 829
urea as bactericide in [Symmers] (25) 150
urethra, [Litthauer] (38) 694
urethra retention catheter in [Rothschild] (90) 928
vision injured from, [Schreiber] (65) 228
war [McWilliams] *1085
WRIGHT, French Academy of Sciences awards prize to 43
stain toning" [Lake] (70) 985
WRIST contracture of terminal phalanges and, symptomatic importance of [Davidenkoff] (49) 1434
WRITING concise 136—C
WRY NECK See Torticollis
WYOMING state board October report, 1053

X

XANTHOPHYLL dependence of color of fat on food rich or poor in, 1119—E
X-RAYS See Roentgen Ray

Y

YAWS See Frambesia
YEAST as food, 1390—E, [Wintz] (85) 1589
food on market not palatable enough to become popular [Schrumpf] (77) 1280
influence of on elimination of uric acid [Salomon] (84) 1589
YELLOW FEVER, [Macfie] (1) 606 667
Arneth counts in [Macfie] (15) 1061
campaign against, in Yquitos, [Romero] (103) 991
immunity to [Carter] (7) 2126
in Australia [Cumpston] 1422—ab
liver failure in malaria and treatment of [Balfour] (29) 2127
YORK Village Maine continuance of health department at, 1392—E

Z

ZELLER'S caustic paste plus silicic acid internally in cancroid of vulva [Reusch] (62) 228
ZEPPELIN raid, 753, 906
ZOLA'S history of Rougon-Macquart family physicians in, [Adams] (16) 1893

AUTHOR INDEX

In this Index, as in the Subject Index the black-face type refers to reading-matter in THE JOURNAL, the light-face to articles in other journals and not abstracted in the Current Medical Literature Department The asterisk (*) preceding the page reference indicates that the original article appeared in THE JOURNAL. The numbers in parentheses indicate the numbered paragraphs on the pages referred to The numbers not in parentheses indicate pages
